COMMON CONGENITAL LESIONS OF THE URINARY TRACT

Edgar Burns, M.D.
and
B. Marvin Harvard, M.D., New Orleans

It is not intended here to present a report on the infinite varieties of congenital anomalies of the urinary tract, but rather to outline a plan of management of two large groups of patients, namely, those with congenital obstructive lesions and those with exstrophy of the bladder, hypospadias or epispadias.

CONGENITAL OBSTRUCTIVE LESIONS

Congenital lesions producing obstruction to the outflow of urine may be found at any point in the urinary tract from the ureteropelvic junction to the urethral meatus. Since they are frequently multiple, it is of utmost importance for one to study all parts of the tract *thoroughly* before instituting a plan of therapy. Surgical relief of obstruction in the upper urinary tract may well be nullified by a comparatively innocent-looking lesion at a lower level. Most commonly, obstructing lesions will be found at or near the ureteropelvic or ureterovesical junction and at the vesical neck.

Congenital obstructions at the ureteropelvic junction are of three general types, although any combination of these may be found in a single patient. They are as follows: (1) *high* insertion of the ureter above the most dependent portion of the pelvis, (2) intrinsic narrowing of the ureteropelvic junction and (3) aberrant vessels, fibrous bands or both, compressing the ureter at or just below the *ureteropelvic* junction. Here again the possibility of multiple lesions demands careful evaluation of the entire urinary tract.

Obstructions at the ureteropelvic junction may occasionally reach clinical proportions in childhood. Most patients, however, will tolerate the lesion until young adulthood when pain, *recurrent pyelonephritis* or a mass in the flank will precipitate investigation. Adequate urologic examination should reveal the site of the lesion, whether it is unilateral or bilateral and important clues as to its inherent nature. If it is unilateral, estimation of the function of the involved kidney is necessary before a decision for or *against* a conservative *surgical* procedure can be made. As a rule, if the affected kidney possesses less than one fourth of its function, the other kidney will usually have undergone compensatory hypertrophy, and nephrectomy will be required. In borderline cases, ultimate evaluation should be deferred until the kidney is exposed at the operating table. Young persons in whom evaluation is equivocal should be given the advantage of a conservative operative trial. Secondary nephrectomy, if necessary, is preferable to primary removal of a potentially useful kidney. The various operative techniques by which plastic repair of the ureteropelvic junction is accomplished are well known. In selection of a technique to be employed it is extremely important to remember that no single operative procedure is applicable to all cases. It is often necessary to combine two or more methods to obtain a successful functional result. The obvious clinical importance of bilateral obstructions at the ureteropelvic junction cannot be overemphasized. Most patients who have come under our care have already suffered considerable loss of renal function, and the condition has usually been complicated by infection. In the treatment of such patients the side with the greater renal damage should be operated on first and the other side operated on without unusual delay, preferably within three months. The reason for this is that once the obstruction on one side is relieved, the function of the opposite kidney fails at a more rapid rate. If it is left untreated, it will soon become a functionless hydronephrotic or pyonephrotic sac.

Congenital obstructive lesions at the ureterovesical junction fall into two categories: those involving only the mucosa and those involving all the layers of the ureteral wall. In the first group, the pressure of urine retained behind the tiny ureteral orifice causes a ballooning of the mucosa into the bladder so that the classical intravesical cyst or ureterocele is produced. Typically, when viewed cystoscopically, the cystic masses appear and disappear in response to ureteral peristaltic pressure, except when the mucosa has been thickened and fixed by chronic infection, in which case the cysts are maintained in their distended state. Roughly, the amount of associated ure-

teral dilatation is proportional to the degree of stenosis of the orifice. Occasionally, the cyst may be of such proportions as to produce acute retention by obstruction of the vesical outlet. In women it may be extruded through the urethra. As a rule these patients, particularly adults, require simple transurethral resection of the cyst. In children, however, because of the small caliber of their urethras and the large size of the ureterocele, suprapubic excision is frequently required.

Fig. 1.—Transvesical meatotomy for bilateral ureterovesical stricture.

The second group of obstructive lesions at the ureterovesical junction, those that involve the entire wall, have in our experience been encountered entirely in children. More commonly, they are bilateral and are associated with pronounced dilatation of the upper urinary tract. There are three methods by which these obstructions may be relieved. The first is by cystoscopic ureteral dilatation, which, in our hands, has been unsatisfactory. The child's urethra frequently will not accommodate instruments of sufficient caliber to make any real impression on the obstruction; general anesthesia is necessary, and dilations must be carried out too frequently to be practical. In the second method, one should free the bladder posteriorly, expose the ureters at their entrance into the wall of the bladder, sever them at this point and reimplant them into the bladder. There are three inherent disadvantages in this procedure: (1) the ureters are dilated and do not lend themselves well to reimplantation; (2) there is a real danger of compromising the blood supply of the severed ureter and (3) the orifices so produced are functionally no better than those produced by simpler methods. Ureteral meatotomy, the third method, may be performed transurethrally if the urethra will accommodate an operating type of child's cystoscope. If there is any question as to the feasibility of this procedure, the operation should be performed suprapubically as depicted in figure 1. The stenosed orifice is incised through the entire area of stricture and the ureteral mucosa is sutured to the vesical mucosa. Ureteral catheters are left indwelling for five to seven days. This method has proved successful in our hands.

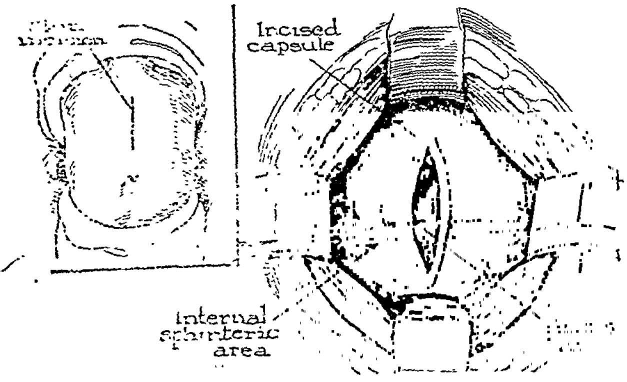

Fig. 2.—Modified retropubic approach to the urethra and vesical neck.

The simple fact that congenital obstructive lesions are often multiple cannot be overemphasized. Not infrequently obstruction at the vesical neck is associated with obtruction at the ureterovesical junction. Preoperative evaluation must include careful examination for residual urine as well as endoscopic examination of the vesical neck. Any obstructive tissue in this area must be removed. It is a common observation that a grossly dilated upper urinary tract in these patients rarely returns to normal after the obstruction has been removed. However, the urine can usually be rendered sterile and further loss of renal function prevented, provided all obstructive lesions have been removed.

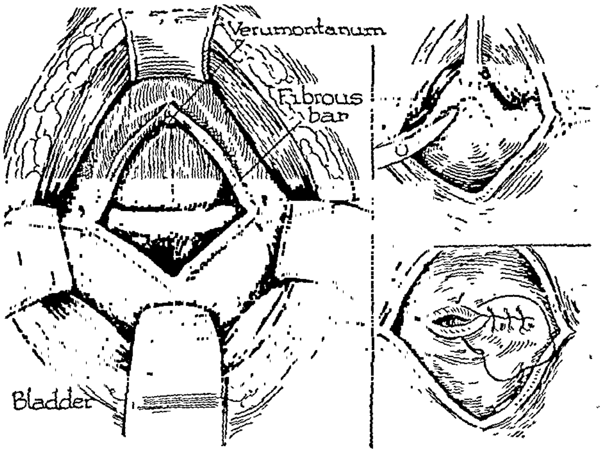

Fig. 3.—Prostatic urethra opened widely from just proximal to the verumontanum to the vesical trigone.

Congenital obstructions to the vesical outlet vary widely but generally fall into one of three large groups. The two commonest types are (1) elevation of the posterior internal sphincteric area simulating the median bar in adults and (2) contracture of the internal vesical orifice. These can occur in both males and females. The third and least common type is congenital prostatic urethral valves. Whatever the immediate lesion, the syndrome of uncomplicated obstruction of the vesical neck is fundamentally the same in each patient, namely, frequency, difficulty, straining and finally acute retention of urine or paradoxical incontinence. The syndrome and the physiopathology associated with it are essentially the same as those observed in men with prostatism. One of the unfortunate aspects of this condition is that frequent voidings or instances of overflow incontinence are all too often interpreted merely as poor training. This lack of understanding of the problem is all the more tragic, for apparently earlier and more rapidly progressive dilatation of the urinary tract is observed in children than in adults. The residual urine predisposes to infection, which, when present, is persistent and increases the rapidity of destruction of renal function. Early recognition of this syndrome and prompt relief of the obstruction offer a good prognosis, but failure to diagnose the condition only leads to irreversible renal damage.

We employ two methods for removal of obstructing tissue at the vesicle neck. The first, transurethral resection, although adequate in some instances, does not provide a satisfactory solution to the problem in all cases. Owing to the inherent technical difficulties in the performance of transurethral resection in children and the frequent necessity for repeated operation because of inadequate removal of tissue, we have been reluctant to use it on any but the simplest cases.

The second method, which we have employed in an increasing number of cases, is a modified retropubic approach (figs. 2 and 3). After exposure of the vesical neck in the classic fashion, a longitudinal incision is made through the vesical neck to expose the vesicourethral junction. The incision may be carried as high in the anterior vesical wall as is necessary for adequate exposure. Similarly, it may be carried down through the anterior wall of the urethra. Such an incision at once provides a wide area for inspection. In males the entire prostatic urethra is visualized from the verumontanum to the trigone. In those patients in whom obstruction is due to a bar of tissue at the posterior vesical lip the offending tissue is removed by simple excision. Enough tissue is cut away to provide a wide outlet that is soft and pliable. Similar excision of tissue is carried out if the lesion is simple contracture of the vesical neck. In each instance the cut margins of the mucosa are approximated with a few hemostatic sutures of fine atraumatic chromic catgut. Prostatic valves, which are usually simple mucosal folds, may be removed by electrocoagulation. If the upper urinary tract is not decompensated, the incision may be sutured primarily with simple sutures of fine atraumatic catgut over a small indwelling urethral catheter. If decompensation of the upper tract has already occurred, suprapubic drainage is employed over a period of months in order to permit maximum return of function.

Fig. 4.—First three stages of Denis Browne technic for repair of hypospadias.

During the past two years we have operated on 12 patients by this method. There have been no instances of postoperative incontinence, nor have there been any other postoperative complications of any importance. Postoperative infections of the urinary tract have been dealt with according to established principles. The duration of postoperative hospitalization has been eight to 12 days. Results to date have been excellent in all patients so treated.

EXSTROPHY OF THE BLADDER

Exstrophy of the bladder is an obvious lesion. The anterior wall of the bladder and overlying abdominal wall are absent; this allows the trigone and whatever remains of the posterior wall of the bladder to bulge forward and rest on the surface just above the level of the symphysis.

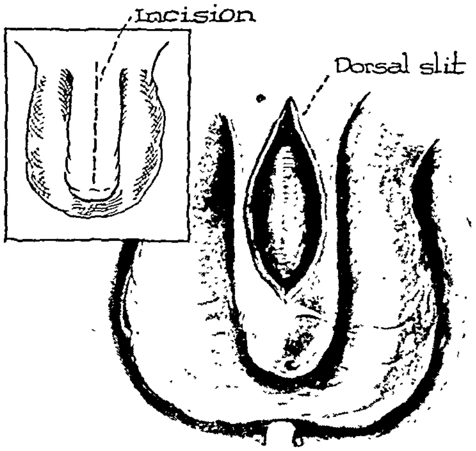

Fig. 5.—Fourth stage of Denis Browne technic.

The lower ends of the rectus muscles with their sheaths are widely separated; this leaves only the peritoneum and a thin layer of intervening fascia between the bladder and the peritoneal cavity.

Treatment of exstrophy of the bladder involves (1) transplantation of the ureters into the rectosigmoid, (2) removal of the bladder and repair of the associated ventral hernia and (3) plastic repair of the associated epispadias in males. In females, if the vagina is rudimentary, the third step is creation of an artificial vagina.

The method by which the ureterosigmoid anastomosis is carried out is a matter of individual choice. Our own preference is a minor modification of the Coffey I technique, which, in our hands, has proved simple and as efficient as more complicated techniques. Whether the ureters are transplanted at one operation or at separate operations is again a matter of individual choice. With present day antibiotics and chemotherapeutic agents there is less reason to fear the serious septic complications that made the two stage operation a necessity a few years ago. Diversion of the urinary stream may be accomplished in patients of all ages even in infants. A

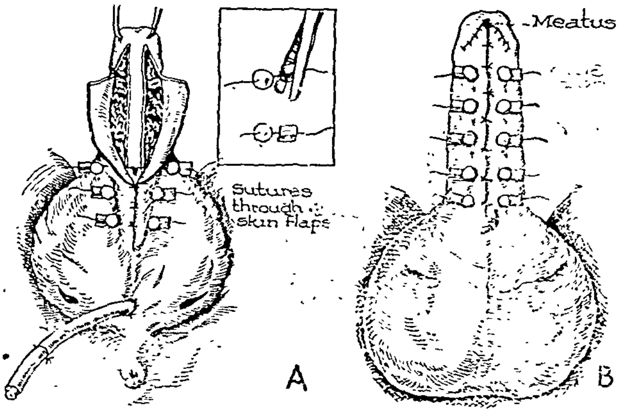

Fig. 6.—Final steps in Denis Browne technic.

months old. As a rule, the earlier treatment is begun, the better; for stenosis of the ureteral orifices develops in a surprising number of these patients. The ureters in such cases undergo early dilatation and lend themselves less favorably to ureterointestinal anastomosis. A few patients seen later in life will show greatly dilated and tortuous ureters. This group will require ureterocutaneous anastomosis.

Excision of the bladder and repair of the ventral hernia should be deferred until the patient has completely recovered from the operation for diversion of the urinary stream. The normal transitional epithelium of the bladder has been converted into a mucous-secreting epithelium in all exstrophic bladders. This epithelium must be removed entirely if success is to be attained in this phase. By removal of the bladder and repair of the hernia, the original defect is converted into another classic lesion, epispadias, and the patient has been prepared for the third and final operation. In females the urethra is of no importance at this stage. However, in many of the males at the time of puberty the ejaculatory ducts will be seen to open onto the surface at the penoabdominal angle with the resultant discharge of semen onto the surface. Plastic reconstruction of the penis and urethra should then be carried out to provide a coital organ. A wide variety of techniques has been employed to accomplish this third phase. We have recently employed with success a simple technique first introduced by Denis Browne (figs. 4, 5 and 6).[1]

HYPOSPADIAS

Hypospadias is a congenital defect in the urethra in which a variable portion of the urethra is absent, the ectopic meatus being situated proximal to the normally placed orifice. There is usually a ventral deformity of the penis produced by a band of fibrous tissue occupying the position of the absent corpus spongiosum. This condition may be divided into three anatomic groups: (1) glandular in which the orifice is located near the frenum, (2) penile in which the orifice is located in the shaft of the penis anywhere between the frenum and the penoscrotal angle and (3) scrotoperineal.

Glandular hypospadias is of little clinical importance unless the orifice becomes stenosed to the point of interfering with micturition, or unless the associated chordee is severe. In the first type, simple meatal dilatation or meatotomy frequently is all that is required. In the penile type the chordee is corrected, and the orifice is displaced proximally on the shaft, a penile hypospadias being thereby created.

In patients with penile and scrotoperineal hypospadias, treatment is surgical, consisting of two phases. The first, relief of the chordee, is accomplished by a transverse incision in the ventral surface of the penis and removal of all restricting bands of tissue. The incision is then closed longitudinally. Attention to detail in this simple procedure cannot be overemphasized. Inadequate performance of this step will seriously jeopardize the outcome of the entire operation.

The second phase is construction of the new urethra. Many techniques have been introduced through the years in an effort to produce as simply as possible a normally functioning urethra. In search of an ideal solution to this problem we have found that the principle embodied in the Denis Browne technique (figs. 4, 5 and 6) seems to lend itself to a simple adaptable method that provides an excellent functioning result. This procedure possesses several advantages over more complicated techniques. After the straightening operation—common to all techniques—has been performed, it is a one stage procedure. It is easily performed and may be completed before the child reaches school age. The average duration of hospitalization is 10 to 14 days, a factor of tremendous economic importance.

The technique of the Denis Browne operation employs a novel method for creating a fully epithelized, soft, pliable urethra. Parallel longitudinal incisions about 0.5 cm. on either side of the median raphe of the penis are carried from the glans to about 0.5 cm. proximal to the urethral meatus and joined in an arcuate fashion. With these incisions as starting points, full thickness skin flaps are produced by lateral dissection until they may be brought together in the midline and sutured without tension. This is accomplished by placement of interrupted silkworm gut sutures as shown in figure 6 A. The skin edges are then sutured with fine chromic catgut. The central island of epithelium, undisturbed, is thus covered completely with a full thickness of penile skin. The distal extremities of the lateral flaps are sutured to previously scarified areas on the ventral surface of the glans, while the proximal extremities of the flaps are brought together and closed to incorporate the hypospadiac meatus in the newly created channel. No catheters or foreign bodies of any kind are left indwelling in the new channel, the urinary stream having been previously diverted by means of perineal urethrostomy. A dorsal longitudinal incision is made over the entire length of the penis in order to reduce all possible tension on the ventral suture line. This incision is allowed to heal secondarily. Only the simplest of gauze dressings is applied for the first few days.

EPISPADIAS

This rare congenital anomaly is seen oftener in males. It is included here because the technique for correction of hypospadias described in the preceding paragraph is also adaptable to correction of the epispadiac deformity. The lesion may be balanotic, penile or "complete." The balanotic type may be mild and require only the simplest methods, as does its hypospadiac counterpart. Similarly, the penile type lends itself to correction by the method already described. However, in the third or "complete" type in which the sphincter is incompetent, the primary requisite is reestablishment of the competency of the sphincteric mechanism. In such cases one may attempt to reestablish the sphincteric mechanism and construct the anterior urethra simultaneously. Failing to secure a competent sphincter, one has no choice save diversion of the urinary stream, preferably to the sigmoid.

SUMMARY

Congenital obstructive lesions of the urinary tract are usually encountered at or near the ureteropelvic or ureterovesical junction and at the vesical neck. Because they are frequently multiple, thorough evaluation of the urinary tract is imperative before institution of therapy.

---

[1] Burns, E.: The Denis Browne Operation for Hypospadias, J. Urol. 64: 382 (Aug.) 1950.

No single operative procedure is applicable to all cases of obstruction at the ureteropelvic junction. One may find it necessary to combine two or more methods in order to obtain a good functional result. If the obstruction is bilateral, the side with the greater renal damage should be operated on first and the other side within three months, if possible.

For obstruction at the ureterovesical junction involving only the mucosa, transurethral resection of the resulting intravesical cyst is usually sufficient, although in children suprapubic excision is frequently required. For obstructions involving the entire wall, which, in our experience, have been encountered only in children, ureteral meatotomy has proved successful in our hands.

Obstructions at the vesical neck must be relieved promptly before irreversible damage takes place. We prefer the modified retropubic approach for removal of these obstructions, although the transurethral approach may be employed. Exstrophy of the bladder is an obvious lesion which is treated by transplantation of the ureters into the rectosigmoid, removal of the bladder and correction of the associated hernia, and plastic repair of the penis.

Of the three types of hypospadias, glandular hypospadias, when the orifice becomes stenosed, requires simple meatal dilatation or meatotomy unless severe chordee is present, in which case it is necessary to convert it to a penile hypospadias, which is treated accordingly. For penile and scrotoperineal hypospadias, treatment consists of surgical correction of the chordee followed by construction of the new urethra. We prefer the Denis Browne technique for this purpose, because it is simple and easy to perform, is capable of completion in the preschool age and has a relatively short postoperative course. Epispadias can be corrected by this same technique.

ADVISABILITY OF SURGICAL REVERSAL OF SEX IN FEMALE PSEUDOHERMAPHRODITISM

Frank Hinman Jr., M.D., San Francisco

Most children with intersexual external genitalia can be converted into acceptable boys or into acceptable girls by appropriate surgical measures. If progressive endocrinologic abnormality is absent, such surgical change will be made to agree with the gonadal sex, unless of course it would have to be made after the attitudes and inclinations of the contrary sex had been established. These generally accepted opinions are the basis for advocacy of early operative exploration of pseudohermaphrodites, so that surgical and psychologic treatment in conformity with the true sex of the gonads can be started before the contrary psychologic pattern is set.[1]

I have no quarrel with the use of gonadal sex as the basis for treatment of male pseudohermaphrodites, although the problem of the genetic female with adenoma tubulare masquerading as a testis has yet to be solved. But the female pseudohermaphrodite, in a high proportion of cases, is the result of progressive androgenic overactivity of the adrenal gland during and after fetal life. This is the significant differentiating fact. This influence, in contrast to the genetic or developmental or maternal influences in the case of other forms of pseudohermaphroditism (table), will continue to act after the period of fetal development. Progressive masculinization after birth can, therefore, be expected in these patients. Of course, a female pseudohermaphrodite can be surgically and psychologically treated in infancy or childhood so that she will react as a female. But she will have the secondary sex characteristics of a boy. She will have a deep voice, a somewhat masculine physique, a beard and hairy body and a receding hair line. Because of these progressive changes, which at present are irreversible by surgical or hormonal means, she will be accepted neither as a male nor as a female.

For this reason of progression of masculinization, the stand that all pseudohermaphrodites be treated according to their gonadal sex must be questioned. The purpose of this paper is to prevent needless phallic sacrifice. The decision must be made from consideration of five aspects: surgical, endocrinologic, psychologic, moral and legal, each of which will be discussed in the light of past experience and present knowledge.

CLINICAL MATERIAL

I have two sources for data bearing on the problem of sex reversal in female pseudohermaphroditism due to adrenal hyperplasia: the experience of previous students and my own experience. This material has been assayed for its surgical, endocrinologic, psychologic, moral and legal values.

The records of the past concerning 149 patients reported on in the literature will be reviewed in detail in a separate communication.

Of interest is the finding that, among 53 patients reported on after they were 15 years of age, 16 were raised as males (four being changed to females just after puberty) and 37 were raised as females (two being changed from males). Five of those raised as boys later married women. There were two who committed suicide because they were prevented from marrying women, as their birth certificates stated they were female. A third of those raised as females were subjected to clitoridectomy.

I have personally observed five children. Two are being surgically altered to live as boys, and three have been operated on by others to become more anatomically feminine.

REPORT OF CASES

CASE 1.—W. K. is now 3½ years old. One sibling with similar genitalia and adrenal insufficiency, died at the age of 4 months. A second sibling, aged 15 months, is a normal girl. The present child was born with a vagina, large clitoris and labia resembling a scrotum. It was felt to be a boy and was so christened. Five days after birth he was discharged from the

From the Division of Surgery, Subdivision of Urology, University of California Medical School, San Francisco.

[1] Melicow, M. M., and Cahill, G. F.: The Role of the Adrenal Cortex in Somatosexual Disturbances in Infants and Children: 9 Clinicopathologic Analyses, J. Clin. Endocrinol. 10: 24-53 (Jan.) 1950. Hooks, C. A.: Clinical Aspects of Intersexuality, J. Urol. 62: 528-534 (Oct.) 1949.

United States Naval Hospital, Oakland, Calif., and was returned 15 days later because of persistent vomiting. He was treated with salt and adrenal cortex extract, and his difficulty was cleared.

At the age of 6 weeks he was admitted to the University of California Hospital, at which time he was noted to have a large clitoris and atresia of the vaginal orifice, with the urethra entering the vagina, which was very large (fig. 1). There was a flat cervix with a patent orifice. The urethra was normal except for its point of entry, and there were folds about the meatus. No verumontanum, ejaculatory ducts or prostate could be found. The bladder was slightly trabeculated. No gonads or adrenal glands were palpated. On rectal examination a prostate could not be felt. Vaginograms were made (fig. 2 *A*). The impression was that this was a female pseudohermaphrodite with adrenal hyperplasia. The bone age was normal, and the 17-ketosteroid excretion was 4.1 mg. in 24 hours (ketonic).

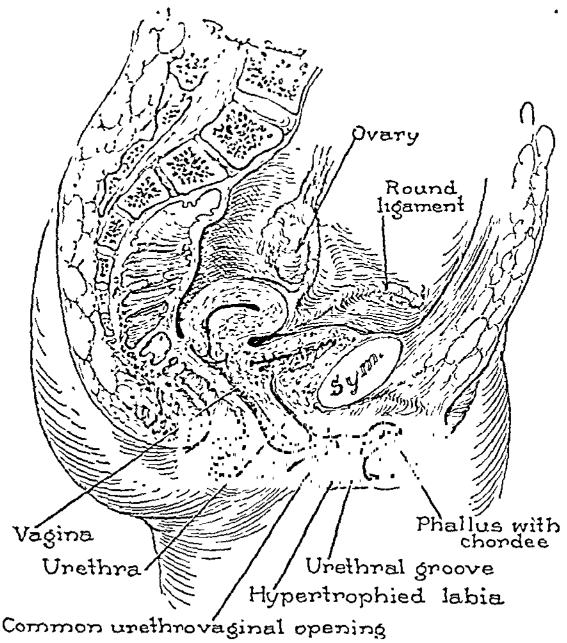

Fig. 1.—Drawing of relation of internal to external genitalia in case 1, typical of female pseudohermaphroditism due to congenital adrenal hyperplasia.

Treatment with an extract of adrenal cortex (eschatin®) alone, salt alone or desoxycorticosterone acetate alone caused persistence of the vomiting. The administration of a combination of desoxycorticosterone acetate, given sublingually, salt and sodium bicarbonate, however, was effective in controlling the adrenal insufficiency.

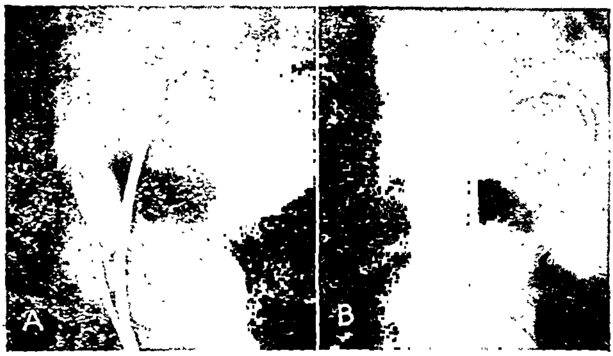

Fig. 2.—Vaginogram with air cystogram, lateral view. *A*, case 1. *B*, case 2.

At the age of 6 months a pellet of desoxycorticosterone acetate (percorten®) was implanted, and at that time the bone age measured 1 year.

The child was readmitted at the age of 1½ years for study with pituitary adrenocorticotropic hormone administration. Treatment with this compound failed to cause the normal eosinophil drop, indicating decreased 11-oxysteroids. The 17-ketosteroid excretion was 4.8 mg. per 24 hours. It was noticed that there were increased erections and masturbation. The parents were advised at this time to raise the child as a boy. A year later psychologic evaluation showed a mental age of 2 years 8 months, an intelligence quotient of 107 and a normal social quotient. His bone age was then 7 years.

The child was readmitted at the age of 3 years (fig. 3 *A*), and a first stage repair of the hypospadias, swinging the prepuce ventrad, was performed with the child under general anesthesia. During the procedure there was carpal spasm, followed by twitching and partial convulsions. A hyperventilation syndrome was considered the most likely cause, and the patient was treated accordingly. However, immediately after operation there was a severe Addisonian crisis, which was treated intensively with salt and adrenal cortex extract. After these difficulties, it was suggested that the second stage operation be performed when the child reached an age at which spinal or caudal anesthesia could be used. The bone age as measured recently (at the chronologic age of 3½ years) was 12 years. Photographs taken postoperatively (figs. 3 *B* and 4 *A*) show a very well developed phallus and masculine physique.

Tentative Classification of Intersexuality

Gonad	Characteristics	Possible* Etiologic Mechanism
Male		
A	Feminine habitus and genitalia except testes and small penis; usually raised as girls	Sex reversal from genetic female (adenoma tubulare)
B	Intersexual genitalia with other anomalies without feminization	Developmental arrest
C	Varying degrees of hypospadias	Excess or abnormal maternal (? adrenal) hormones
Female		
A	Intersexual genitalia without progressive masculinization	Genic disturbance
B	Intersexual genitalia with other anomalies without progressive masculinization	Developmental arrest
C	Intersexual genitalia with progressive masculinization	Excess androgenic function of fetal adrenal gland
Both Male and Female		
A	Intersexual internal and external genitalia without progression	Developmental arrest or genic disturbance of gonad

---

* The respective roles of mutation, developmental arrest and maternal hormones cannot be discussed here. However, such factors may not be mutually exclusive.

Summary.—A 3½ year old female pseudohermaphrodite had a sibling with a similar deformity. The patient's masculinization was progressive, so that at the age of 3½ years he had profuse genital hair, a large phallus, advanced bone age (12 years) and slightly elevated 17-ketosteroids. He had, in addition, moderate adrenal cortex insufficiency controlled by subcutaneous implantation of pellets of desoxycorticosterone acetate. The hypospadias was corrected surgically, with the intention of continuing to raise the child as a boy.

Case 2.—A. B. is also now 3½ years old. An older brother, genitalia not described, died at the age of 3 months of dehydration and vomiting ascribed to "pylorospasm." An older sister is normal. At birth it was noticed that the labia were swollen and that the patient had a very large clitoris, which grew rapidly after birth. The child was admitted to the University of California Hospital at the age of 3 weeks with adrenal cortex insufficiency. Treatment was with saline solution, desoxycorticosterone acetate and an extract of adrenal cortex. Panendoscopy showed that the urethra and vagina opened into a short common passage exactly similar to that in case 1. Vaginograms with air cystogram showed the relationship between the vagina and the bladder (fig. 2 *B*). 17-Ketosteroid excretion was 15.9 mg. per 24 hours (ketonic), 8 per cent of which was dehydroandrosterone. The patient was discharged with the diagnosis of adrenogenital syndrome in a female infant. During the first year of life, in Oklahoma, peritoneoscopy was done, which was not diagnostic.

Readmission occurred at the age of 2 years, at which time pellets of desoxycorticosterone acetate were implanted to combat the chronic adrenal insufficiency, oral treatment for which was begun in Oklahoma. Exploratory laparotomy (Dr. H. F. Traut) revealed bilateral cystic ovaries, normal uterus and tubes and questionably normal adrenal glands. Sections were read as showing normal infant ovarian tissue. The bone age at this time was 5 to 5½ years. The crines were well developed, and the general body form already appeared somewhat masculine (fig. 5 *A*). The child was discharged to be raised as a boy, named Allen rather than Anita.

Dr. Lawson Wilkins, in a letter at this time (Jan. 31, 1949) suggested, on the one hand, raising the child as a girl if she were older and had already been raised that way, but that in this case raising her as a boy would present fewer problems in later life. He suggested that the ovaries and uterus might later be removed. Consequently, the birth certificate was changed by affidavit without difficulty.

A first stage hypospadias repair was done at the age of 2¾ years. Considerable oozing occurred during the operation so that transfusion was necessary, but no signs of adrenal insufficiency were encountered. The child was readmitted at the age of 3¼ years for control of the adrenal insufficiency. His parents noted that he was making a much better adjustment as a boy than he had as a girl. His bone age was 12 years at this time, and the 17-ketosteroid excretion was 25.9 mg. per 24 hours. At present he is maintained on 2 to 4 drops of desoxycorticosterone in oil (cortate®) a day and has a 75 mg. pellet of desoxycorticosterone acetate implanted subcutaneously. Photographs (figs. 4 *B* and 5 *B*) show his present genital and bodily status.

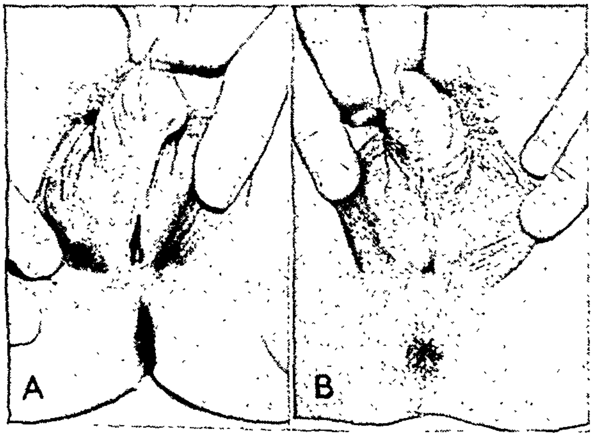

Fig. 3 (case 1).—External genitalia: *A*, preoperative, 3 years of age. *B*, postoperative, 3½ years of age.

Summary.—A female pseudohermaphrodite, with a sibling who had adrenal insufficiency, and with progressive masculinization (increased 17-ketosteroid excretion, increased bone age, gross genital hair, large phallus and masculinized physique), was subjected to a first stage repair of hypospadias in order better to raise the child as a boy.

Case 3.—S. F. C. is now 18 years old. She was first admitted to the University of California Hospital at the age of 5½ years, with the history that at birth abnormal genitalia and at 3 years abnormally rapid growth had been noted. There had been no feeding problem, however. On examination she was observed to have moderate hirsutism, a common passageway for the urethral and vaginal openings and, on rectal examination, a uterus. Her bone age at that time was 10 years. Perirenal air insufflation showed possibly enlarged adrenal glands. At this time adrenal exploration was carried out through the bilateral lumbar approach of Young. The left gland was twice normal size, and two thirds of it was removed. The right gland appeared normal, but a small adenoma was resected from its surface. Exploratory laparotomy revealed normal uterus and tubes; therefore, a plastic operation was done to remove the clitoris and expose the vagina. The child was readmitted at the age of 8½ years, even more masculinized than before. She was having considerable difficulty adjusting socially, since her voice was deep and she had acne and masculine breasts. Air insufflation was again done, which showed a right adrenal shadow the same size as before, with some calcification. X-ray therapy was given to this adrenal gland (3,127 tissue r) with questionable improvement thereafter. 17-Ketosteroids at this time were 13.9 mg. per 24 hours (ketonic). The following year ethinyl estradiol, 0.05 mg. twice a day, was given. The 17-ketosteroids were then 23.7 mg. per 24 hours (ketonic). It is noted that the only clearcut improvement was a reduction in the severity of the acne. The child was admitted at the age of 9½ for removal of the remaining third of the left adrenal gland. There was no postoperative Addisonian difficulty. The 17-ketosteroid excretion postoperatively was 10.7 mg. per 24 hours (ketonic).

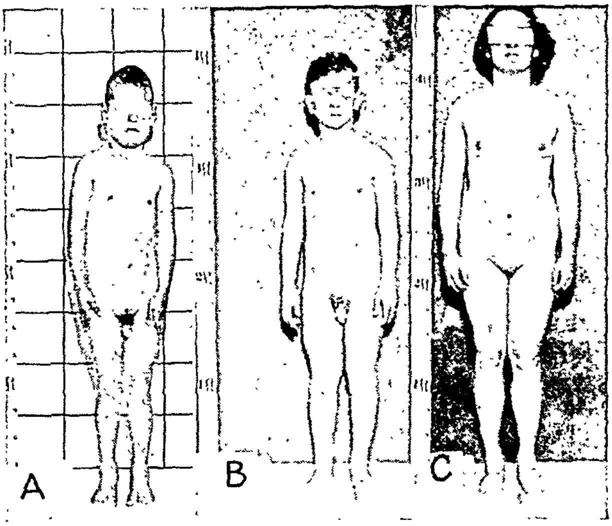

Fig. 4.—*A*, W. K. (case 1), 3½ years of age. *B*, A. B. (case 2), 3½ years of age. *C*, S. F. C. (case 3), 18 years of age.

Readmission occurred at the age of 13. In the interval she had become more female in her likes and dislikes, and it was felt that her body was more rounded. However, an increase in bodily hair and little change in the depth of her voice were noted. She was constantly harrassed by the other children, who commented on her hairiness. She was given diethylstilbestrol, 1 mg. three times a day, for a month without effect. 17-Ketosteroid excretion was now 68.7 mg. per 24 hours (ketonic). The bone age was 17 years. Further estrogen therapy caused some growth of the breasts, especially of the nipples, with pigmentation in this area, but the comment is made that there was increased hirsutism, which caused her mother great concern. At

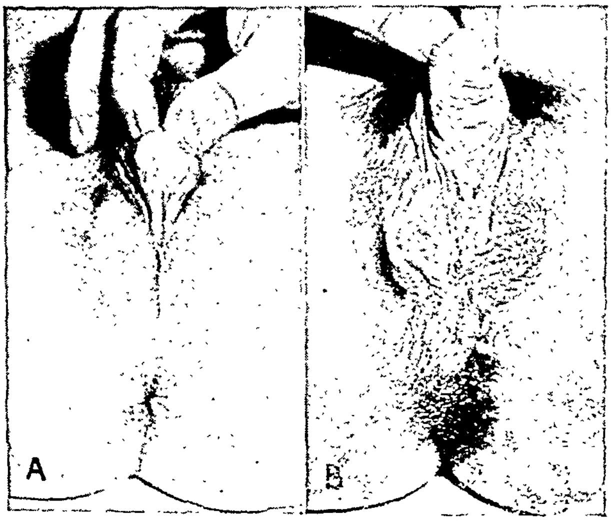

Fig. 5 (case 2)—External genitalia: *A*, preoperative, age 2 years. *B*, postoperative, age 3½ years.

the age of 18, premarin[5] (estrogenic substances [water soluble]) was given, 2.5 mg. twice a day in short courses, which resulted in menstrual spotting. A photograph is shown of her present state of development (fig. 4 *C*).

Summary.—An 18 year old female pseudohermaphrodite has had repeated partial adrenalectomy and hormone therapy, as well as clitoridectomy, without arrest of the progressive masculinization.

CASE 4.[2]—D. G. Y. is now 11 years of age. She was felt to be a girl at birth and has a sister two years younger, also with pseudohermaphroditism (case 5). D. G. Y. was admitted to the University of California Hospital at the age of 3½, having had pyelitis every three to four months for the previous year. At first, soon after birth, she had been a feeding problem and had vomited, but this had not recurred. At the age of 1½ years she had a circumcision of the clitoris because cysts had been noted beneath the prepuce. On admission a large clitoris was noted, with a single opening beneath it. The labia minora were adherent to the clitoris. Study showed a normal bladder and urethra, except that the urethra emptied into the anterior wall of the vagina, forming a urogenital sinus. The uterus and cervix were present and felt normal. The pyelitis was cleared, and the patient was discharged.

Two months later the patient was readmitted, and an exploratory laparotomy was performed (Dr. H. F. Traut). This revealed normal uterus, tubes and ovaries with follicles. The clitoris was amputated. At the age of 4 years the bone age was noted to be 8.3 years. 17-Ketosteroid excretion, measured at the age of 5 years, was 12 mg. per 24 hours (ketonic). The clitoris at this time had regrown.

Since that time the child has continued to be masculinized. Two more clitoral amputations have been necessary because of regrowth of the phallic stump. Recently the mother has had difficulty curbing her children's questions and anxiety concerning their unusual bodily state, and so far she has refused to have them photographed again.

CASE 5.—D. K. Y. is 8 years old at present. She, as was her sister (case 4), was called a female at birth. She was admitted to the University of California Hospital at 3 months of age. She had a clitoris 2.5 cm. long with scrotal folds for labia, a urethral groove and a single urogenital sinus. With the child under anesthesia, the ovaries were questionably palpable but the uterus was felt to be present. A common urogenital sinus and a large uterus were seen on hysterogram. She was readmitted one month later for exploratory laparotomy (Dr. H. F. Traut). As in her sister, normal ovaries with follicles were found and the clitoris was amputated. Later, revision of the vagina was suggested. At the age of 7 months there was pubic hair, and the bone age at 21 months was 27 months. The 17-ketosteroid excretion was 9.9 mg. (ketonic), which rose three months later to 16.1 mg. per 24 hours, and it was noted at this time (age 2 years) that the clitoris had regrown.

Like her sister, this patient physically has been progressively masculinized, although her interests and inclinations continue to match her environmental sex. She will continue to be brought up as a female.

Summary.—These two female pseudohermaphrodites have become progressively masculinized, but, since ovaries were found at laparotomy, they have been subjected to clitoridectomy and raised as girls. Their excessive physical masculinization at present (aged 11 and 8 years, respectively) may make one question the advantages gained by this course.

These five cases allow some comparison between patients with the congenital adrenogenital syndrome raised as boys and those raised as girls. Examination of the photographs shows that surgical treatment is more effective if it can go along with the patient's hormonal development (hypospadias repair in cases 1 and 2) rather than against it (clitoridectomy in cases 3, 4 and 5). It is, of course, impossible to estimate the ease of adjustment of the boys when they reach the critical age of puberty, but they have adjusted very readily so far. The girls, however, have actually been observed to adjust poorly with their classmates.

COMMENT

It seems obvious that one cannot decide at birth (1) that the deformity is due to adrenal overactivity or (2) that if it is it will be progressive. 17-Ketosteroid determinations do not become sufficiently elevated for months; bone age is normal, and secondary sex characteristics are still dormant—these being the criteria to be used in assessing progression. However, by the age of 2 years, these three signs will be manifest if progressive adrenogenital masculinization is to occur. If doubt exists (I felt the presumptive evidence so strong in one of the cases, case 2, that abdominal exploration was not performed), laparotomy is done to ascertain the presence of ovaries and hyperplastic adrenal glands. And it is at this age—before irreversible social and psychic changes have taken place—that the decision as to sex must be made, to be determined on surgical, endocrinologic, psychologic, moral and legal grounds.

Surgical Aspects.—The anatomic condition in these patients is illustrated in figure 1. The phallus, although even larger than that of a boy of similar age, is held down in ventral chordee. If the patient is to be made a boy, this chordee is released in an exactly similar manner to that employed for perineal hypospadias. There is only one previous report of use of this procedure for treatment of female pseudohermaphroditism [3]; I used such a technique in two of my patients (cases 1 and 2). The urogenital sinus, into which both vagina and urethra open, is utilized as a continuation of the urethra, allowing the use of a modified Wehrbein operation to bring this passage to the end of the phallus. The result should be indistinguishable from that after repair of extreme degrees of hypospadias. The presence of the vagina is not of consequence, as has been shown by Cecil [4] in cases of extreme hypospadias. Progressive masculinizing influences will maintain the phallus proportionate to the development of the body, so that at puberty the boy will have a serviceable penis.

On the other hand, if it is desired to reverse the hormonal trend and raise the child as a girl, clitoridectomy (perhaps repeated) is done, followed by a plastic operation to expose the vagina at its point of juncture with the urogenital sinus, as described by Young.[3]

In either case present surgical technique allows construction of functional external genitalia suitable for the chosen sex.

Endocrinologic Aspects.—With the congenital adrenogenital syndrome two facts must be faced: that there will usually be progressive masculinization, and that this trend cannot be reversed by surgical means.

Of course, female infants with milder degrees of pseudohermaphroditism in whom progression of masculinization does not occur will be passed over by parents and by authors, so that the literature and individual clinical experience will be weighted in favor of progression. But most patients observed after the age of 2 years who show evidence of excess androgen secretion at that time (advanced bone age, increasingly large phallus, hirsutism and high 17-ketosteroid excretion) will show progression throughout prepuberal life.

[4] Cecil, A. B.: Surgical Management of Vagina in Male Construction in Hermaphrodites, J. Urol. 62: 709-712, 1949.

Partial adrenal resection, while perhaps logical in theory, has been disappointing as a therapeutic measure in the 12 reported cases. Most of the patients were operated on after puberty, however. As Young [3] suggested, better results might be expected if excision were carried out before that time. Also, apparently inadequate amounts of tissue were removed, since on the one hand no cases of postoperative adrenal insufficiency have been reported among these 12 patients and, on the other, seldom significant, and never permanent, lowering of 17-ketosteroid excretion was obtained. The combination of subtotal excision with judiciously metered roentgen radiation after operation has yet to be fully exploited, although in case 3 it was not particularly effective. Interpretation of results of partial adrenalectomy must be tempered by the realization that patients who subject themselves to the procedure often have a very strong desire to become more feminine and will interpret minor postoperative improvement accordingly. The fact that a decrease of 17-ketosteroid excretion to levels even approaching normal has not occurred makes one hesitant about accepting reports of improvement, especially since the patients have usually been followed only a short time.

Hormonal therapy, especially the administration of estrogens, has been, of course, tried by many in an attempt to neutralize the excess androgens or to bring out feminine secondary sex characteristics. The usual effect is increased size of the breasts, especially of the nipples, which become protuberant and pigmented. One of the present patients (case 3) had a better mammary response than that illustrated in published works. In some cases there is decreased hirsutism or higher-pitched voice, but these changes are open to the same criticism as are those from partial adrenalectomy. Occasionally, hirsutism increases. The case of the child to whom diethylstilbestrol was given at the age of 5 well illustrates the dangers of early administration, for the epiphyses closed even more rapidly than is usual in these cases.

So far, attempts have been made to use estrogens directly or indirectly to antagonize the androgens. The expected feminization has not been forthcoming. A more rational experimental approach is the attempt to inhibit the adrenal cortex cells themselves, and so decrease the excess excretion of androgens. It has been suggested [5] that desoxycorticosterone might have this effect, and compound E, through its "S" hormone action of antagonism to the androgenic "N" hormones, has been proposed.[6] The use of cortisone in a 15 year old female pseudohermaphrodite has recently been reported by Wilkins.[7] He obtained notable reduction in 17-ketosteroid excretion during the 15 day period of administration, but the level rose again 11 days after cessation of treatment. A personal communication from Wilkins indicates that administration of 25 mg. of cortisone daily to these patients will cause feminization and menstruation. Whether this compound is safe enough to give over long periods has yet to be shown, but it may be most useful in those female pseudohermaphrodites who have been raised as or altered to be girls. Whether it should be administered to children with strong masculine social and psychologic trends might be questioned.[7a]

Psychologic Aspects.—Modern, in contrast to nineteenth century, psychiatric thought ascribes to the hormones the quantity of sexual drive but reserves for psychologic and environmental forces the direction of that drive.[8] It is the psyche that chooses the sex object,[9] although biologic factors play a minor role [10] by marshaling the psyche to follow the somatic characteristics. It was apparent from perusal of the reported cases that 30 per cent of the patients were raised as males without reported conflict; and, perhaps more important, only one was reversed once he had reached puberty. Thus, masculinity was usually not so burdensome that later reversal was desirable or necessary.

Similarly, Ellis,[8] in his attempt to find the basis for sexual choice in homosexual persons, studied the sex objects of true hermaphrodites and pseudohermaphrodites. Significantly, female pseudohermaphrodites with adrenal hyperplasia, if raised as males, were all heterosexual (chose women as sex objects), whereas if raised as females they occasionally were bisexual (chose both men and women for sex objects). This adds to the evidence for raising these persons as males.

In summary, present psychologic data indicate that a person seen early enough (before the age of 2 or 3 years) will fit best in the sex in which he has been arbitrarily raised.

Moral Aspects.—The attitude of society toward intersexuality has gone through two great phases. In ancient times, incest was the most universally repugnant moral crime and perversion was even condoned. In more modern times, on the other hand, perversion has become increasingly immoral and incest, while certainly not condoned, is looked on with slightly less abhorrence.

Ancient Jewish codes formulated religious rules for intersexes that were not particularly discriminatory. For example, in the Talmud (Tract Sabbath, Chapter 19, Mishna 3) the exception is made for the hermaphrodite that the Sabbath must not be desecrated by his precircumcisional or postcircumcisional bath. Also, the laws of uncleanliness did not apply to him.

In early Roman times hermaphrodites were regarded as omens of bad luck, but later there was a reversal of attitude and they were even allowed to marry.

Contemporary religious thought apparently is at two poles, with some representatives of the Roman Catholic Church on the side opposite those of most other churches. One of the Society of Jesus would formulate the Church's position with regard to the reversal of sex of the female pseudohermaphrodite as follows: 1. The actual or genetic sex is never changed. Notwithstanding

her education as a male, etc., she could never be "converted" into a male. 2. There is an essential difference in the education of a male and that of a female. 3. Male education tends directly to make a person sexually attracted to females. 4. It is morally objectionable to raise a female to be sexually attracted to females. Such an education results directly in homosexual tendencies. The conclusion is that it is morally objectionable to raise a female pseudohermaphrodite as a male.

Representatives of the Episcopal Church, on the other hand, feel that there does not appear to be any religious factor involved, other than the requirement that the person be given the fullest opportunity for spiritual integrity and development. The ethical problem is closely parallel, in that any decision in regard to an individual case should be indicated by the possibilities for the fullest and more normal opportunities for development.

The practical application of this knowledge is illustrated by two cases. De Crecchio[11] in 1865 described a female pseudohermaphrodite with hyperplastic adrenal glands, by occupation a valet, who was christened as a female but was raised as a boy. When refused the sacrament of marriage with the young girl of his choice, he is reported to have died some 20 years later of dissipation. Quinby[12] and Young[3] described a similar patient, who at the age of 31, having been forbidden to marry by a priest, committed suicide by taking mercury bichloride. One would be well advised to avoid sex reversal in members of certain religious groups.

Legal Aspects.—The law has tended in general to follow the moral and religious attitudes of the period.

In ancient times the hermaphrodite was left fairly free to choose his sex, although special legislation occasionally was formulated.

Old English law[13] demanded that the hermaphrodite decide the sex he will adopt, with the penalty of death imposed if he should change. This concept has been carried down to the present with little alteration. Prussian law of the eighteenth and nineteenth centuries removed the decision from the individual person and gave it to the parents. Medical opinion was advisory only, since the doctor was little better equipped to determine the sex than the layman. However, in modern times the informed physician, through the medium of the birth certificate, is required to determine the sex in which the person is to be reared. Since it is the doctor who signs that certificate, he is free to alter it if later he accumulates contrary evidence.

There is apparently nothing in legal precedent that makes the gonads the prime sex determinant, although usually such is the case. Lawyers are of the opinion, although they will not be bound by it, that, with the advance of medical science, sex should be based on more than the presence of male or female gonads. Physical factors, as well as hormonal and environmental influences, play an important role.

For his own protection, the physician should of course have written permission from both parents and be assured of their full understanding and consent. Also, he should have the birth certificate changed, which is done in most states by mere submission of forms.

Since inheritance and property laws no longer discriminate so sharply between male and female, the only real legal difficulty a sexually reversed pseudohermaphrodite will meet comes at the time of his marriage. To marry without informing his spouse of his sterility would be grounds for annulment. The necessity of informing her of his gonadal incongruity does not seem absolute, although the legality of withholding this information has not been tested.

In addition, if a pseudohermaphrodite breaks the law through sexual activity or perversion, it will be as a female acting aggressively as a male rather than as a male submitting in the role of a female. Broster[14] writes that in England a male may not masquerade as a female *but* a female may act as a male.

In summary, the law would allow sex determination by a summation of gonadal, hormonal and environmental factors. Once established as of one sex or the other, the person is no longer free to return to the opposite sex without appropriate legal action.

SUMMARY AND CONCLUSIONS

Female pseudohermaphroditism from adrenal hyperplasia is usually a progressive masculinizing disorder, as in the five cases presented.

At the age of approximately 2 years, four criteria will allow determination of the degree and direction of the progression: (*a*) advanced bone age, (*b*) increasing size of phallus, (*c*) hirsutism and (*d*) elevated 17-ketosteroid excretion.

If progression is evident, consideration must be given to the preferability of raising the child as either a masculinized female or a sterile male with ovaries. Even though it seems preferable to raise the child as a female, the surgeon is strongly urged to defer clitoridectomy until puberty to be certain that the factors favoring ultimate feminization will still be present. Five illustrative cases are presented.

Partial adrenalectomy and estrogen therapy have not been particularly useful in inhibiting masculinization or in effecting feminization. Cortisone is promising as an agent to suppress excessive androgen production and to allow feminization. It may be of use in children treated before masculine social and psychologic attitudes are established and could be especially useful in children already raised as females.

Female pseudohermaphrodites will usually fit psychically into the sex in which they are arbitrarily raised.

Except for the attitude of the Roman Catholic Church, there appears to be no moral objection to raising these persons in either sex.

If due provision is made for obtaining written permission from the parents and for changing the birth certificate, there appears to be no legal obstacle to the choice of either sex.

Consequently, if an intersexual child shows progressive masculinization, clitoridectomy should be deferred until thorough trial of cortisone is made. In children seen after masculine social and psychologic trends are established, repair of hypospadias so that the development may proceed as in a boy may be the better choice; this was done in two personal cases.

ABSTRACT OF DISCUSSION

ON PAPERS BY DRS. BURNS AND HINMAN

Dr. Frank Hinman, San Francisco: I would like to discuss the cases of exstrophy. As Dr. Burns said, we are now transplanting ureters at a much earlier period in children, and these are developmental anomalies, entirely different from the cases discussed in the second paper, which are endocrinological. These persons with exstrophy are definitely either male or female. They have normal functioning testes, or they have normal functioning ovaries. Repair of the hypospadias has ordinarily been done, with removal of the bladder, when these children are young, and a urethra is built with the idea that they may have seminal competence. A good urethra can be built, but this urethra does not function until these male children reach puberty. As a rule, it closes up. A definite atresia of the urethra occurs, so that when the person has an ejaculation there is no way for the ejaculate to get to the outside. It is completely occluded. And so with the girls; often they have an anomaly involving the vaginal outlet but the upper vagina and urterus are perfectly normal. They have a good normal uterus, and they have normal ovaries. We have had as patients two or three of these girls who grew to womanhood and married: One of them has had two children by cesarean section; one other has had a child. So far as their sex life is concerned, it should be respected as it is in the boy. My plea would be that, in the young boys, remove the bladder by cystectomy, but do not repair the hypospadias until they reach puberty. After they reach puberty and you build a urethra, there will be some opportunity for this urethra to be kept open so that they will have a seminal tract, and when they marry they can have a family and lead a normal sex life. A boy had his ureters transplanted when he was 6 years old; when he grew older, he was unable to have an ejaculation. He finally married and was in considerable misery. We attempted again to build a urethra, but it was too late and we were unsuccessful. The only thing we could do was to tie his vas in some hope that it might relieve him. In another case a girl had her ureters transplanted when she was about 6 years old. Later when she married, she was unable to have intercourse. We did not see her until she was 19 years of age. When she had started to menstruate, she had had apparently a hematocolpos, and her doctor, thinking she could not have children anyway, did a hysterectomy. It would have been a simple thing then to have built a vagina for this girl, as was done later. There was no reason that she could not have had children. This paper of Frank Hinman Jr. brings up food for thought. This, of course, is a special type of case—adrenal hyperplasia. There are conditions that result in masculinization in the female, such as adrenoblastoma of the ovaries, some disturbances of the pituitary and adenoma of the adrenal gland. We know that when there is adenoma of the adrenal gland, with disturbance of function we can remove the tumor and cure the patient, but here we have a progressive adrenal hyperplasia. When a person is born, he gets an X or Y chromosome from the parents. The male has the X-Y chromosome, and the female has the XX chromosome, so the male may have the X-Y and the female the XX. That is a genetic factor. Dr. Hinman has shown definitely that, even though children at 2 years of age are genetically females, they will have a congenital excess of androgenic activity from a hyperfunctioning adrenal gland, and they will continue to have this androgen stimulation all their lives. I think he makes a good point, that they should be considered with respect to what their best future happiness will be, and probably a great many of them will be much happier if raised as males than if raised as females, even though they are genetically females.

Dr. Jay J. Crane, Los Angeles: Dr. Burns has emphasized the frequency with which we see patients, usually very young children, suffering with congenitally enlarged, dilated, elongated and kinked ureters, associated with renal insufficiency and chronic pyelonephritis. The fact that the condition is usually bilateral speaks for its congenital origin. The term congenital neuromuscular dysfunction amply describes the pathological state of the ureters but does not portray the clinical aspects of the disease, which is so difficult to treat and so often fatal. By the time the urologist has had the opportunity to study these young patients, the pathological picture is often so far advanced that it is difficult, if not impossible, to establish the true causation with any degree of certainty; however, in the true cases of congenital megaloureters or neuromuscular dysfunction of the ureter, there are often associated neurological findings in the gastrointestinal tract. Therefore, I believe that a complete gastrointestinal study in these young persons will be of great benefit in establishing the true diagnosis and will assist greatly in prognosticating their recovery. I agree with Dr. Hinman that we should make haste slowly in deciding what sex female pseudohermaphrodites will turn out to be eventually. The information and advice given to the parents early are of paramount importance. Dr. Hinman has made an excellent presentation. I believe that any physician before treating these unfortunate persons should ponder a long time before doing anything more radical than an abdominal exploratory operation. Certainly, before the clitoris is amputated, the patient should have the benefit of a very thorough endocrinological study.

Dr. Edgar Burns, New Orleans: In regard to the management of patients with exstrophy of the bladder, it is important to give careful attention to the competency of the rectal sphincter. As a rule, the rectal sphincter in these patients is competent, but we have had two cases in which there was inadequate control after the ureters were transplanted into the rectosigmoid, and a plastic procedure had to be done on the rectum. This, of course, should be known before the ureters are transferred to the intestinal tract. We have resected the elongated, tortuous ureters in two cases. We believe, however, that this should be deferred until after all obstruction has been removed, because in these cases the ureters have a tendency to contract downward. In so contracting, they shorten, and it is not necessary in a great many cases to resect portions of the ureters themselves. In a few cases there will be adhesions between the loops of tortuous ureters, and, of course, when that occurs the kinks will remain and drainage from the kidneys may be inadequate. I would hesitate very much to do a nephrostomy because the kidneys in these cases have already been damaged and in the process of inserting a nephrostomy tube through the cortex, further damage to already impaired renal tissue will necessarily occur.

Airborne Infection.—The importance of air as a mode of spread of naturally occurring disease has been a long disputed question. Prior to 1890, it was a general belief, both among scientifically informed persons and the general public, that the air was the dominant mode of spread of infection. This is indicated by the general terms "miasma" meaning noxious vapors and "malaria" meaning bad air. With the advent of bacteriology, however, this belief rapidly disappeared. Although bacteria were found in air by Pasteur, these turned out to be mostly harmless saprophytes. Thorough studies of bacteria in the air were conducted by Fluegge and others in Europe and by Chapin and Winslow and others in this country. It was shown that whole rooms, or even buildings, could be readily contaminated by a spray of such harmless organisms as B. prodigiosus, but the weight of the evidence suggested that most pathogenic bacteria either rapidly died or lost their virulence when exposed to air. The attitude of most informed workers in the field swung strongly away from the concept of airborne infection toward the importance of contact and droplets. This attitude has remained the dominant concept up to the present time. Alexander D. Langmuir, M.D., The Potentialities of Biological Warfare Against Man, *Public Health Reports*, March 30, 1951.

FRACTURES OF THE HUMERUS

Carl Davis Jr., M.D., Chicago

The purpose of this paper is to present some of the problems and treatment of fractures of the humerus which frequently confront the general practitioner, physician and surgeon in everyday life. Nobody should fail to evaluate carefully, by physical and roentgenologic examination, the location and extent of the fracture, as well as the degree of injury to the soft tissues. Shock when present is treated with adequate supportive measures. Pain is relieved with appropriate medication. The treatment of fractures of the arm is dependent not only on the type of fracture but on other considerations such as age, general physical makeup and the economic situation of the patient. The knowledge of simple principles of nonoperative treatment will result in early and complete reduction in most instances. In the event of operative intervention, a competent surgical consultant must be called. The subjects in this report include fractures of the upper arm and the midhumerus and injuries about the elbow that involve the lower end of the humerus.

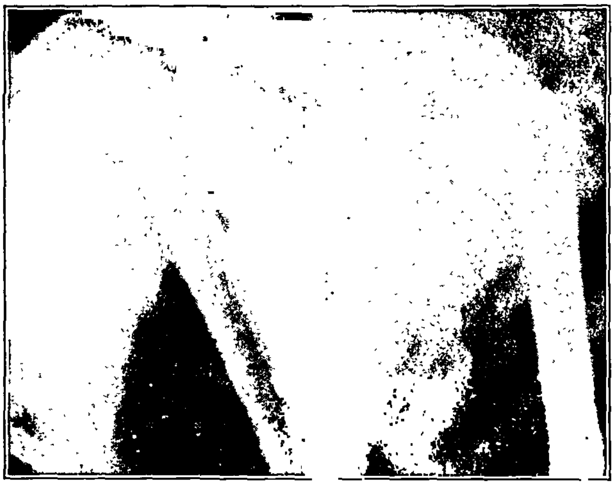

Fig. 1.—Original roentgenograms of fracture of the surgical neck of the humerus in a boy, age 12. Hanging cast was used.

FRACTURE OF THE SURGICAL NECK

One of the common injuries of the upper arm in young children and adults is a fracture of the surgical neck of the humerus. In most instances the patient falls on the outstretched hand. The arm is forced into abduction or adduction, and a corresponding fracture is the result. The adduction fracture is commonest in children (figs. 1 through 3). Occasionally there is impaction of the fragments which makes the treatment simple, but in many cases the short upper fragment is abducted and externally rotated by the supraspinatus muscle, and the long distal one is pulled inward by the action of the strong pectoralis major, teres major and latissimus dorsi muscles and displaced upward by the coracobrachialis and long head of the triceps muscles.

In the management of these cases two courses may be followed. If there is impaction of the fragments, a small pad is placed in the axilla, and the shoulder and arm are immobilized by a shoulder cap plaster splint which extends posteriorly down to the hand with the forearm flexed at a right angle. The upper arm is then fixed to the chest by a gauze dressing or elastic bandage while the forearm is held by a sling. This position is maintained four to six weeks. After this time, the splint having been removed, the arm is carried in a sling; active motion is encouraged, and physiotherapy started.

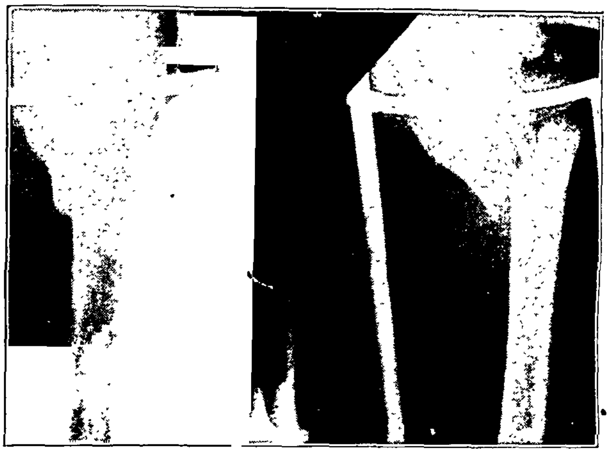

Fig. 2.—Patient was first seen 10 days after injury. Manipulation with the patient under anesthesia and traction with the arm supported in a Thomas splint failed to give satisfactory reduction.

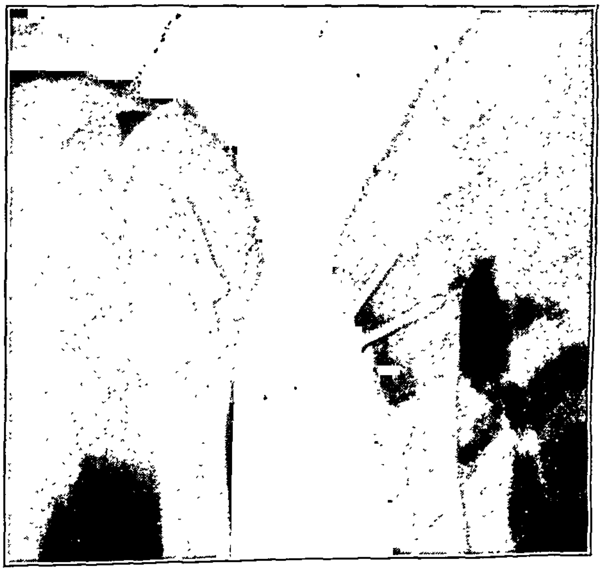

Fig. 3.—Operative intervention resulted in good reduction. Nine months postoperatively there was union of the fracture with good function of the shoulder and arm.

If there is displacement and overriding of the fragments, the fracture is manipulated with the patient under

---

From the Department of Surgery, University of Illinois College of Medicine (Rush) and the Presbyterian Hospital and the Cook County Children's Hospital.

Read before the Section on General Practice at the Ninety-Ninth Annual Session of the American Medical Association, San Francisco, June 29, 1950.

general anesthesia. The arm is then held in abduction at the required angle, as demonstrated by the roentgenogram, and immobilized in traction in a Thomas arm splint (fig. 4) until the roentgenograms indicate enough callus to free the arm safely from its traction support. An additional period of immobilization with a shoulder spica is carried out with the arm abducted 45 to 60 degrees. Some believe that a sling may be adequate instead of shoulder spica. However, it is my belief that in children the shoulder spica is used to advantage. This treatment has given a high percentage of good results. Caldwell and Smith[1] have recommended the insertion of a small Steinmann pin through the olecranon (the elbow is flexed at 90 degrees) in the treatment of unimpacted fractures of the surgical neck of the humerus where the reduction by manipulation is unsuccessful. The value of early active motion of the shoulder and elbow after union has developed is well recognized in the treatment of these cases.

The "hanging cast" was first suggested by J. A. Caldwell[2] for treatment of fractures of the shaft of the humerus. The hanging plaster cast is applied from the midarm to the wrist with the elbow flexed to a right angle and the forearm in midposition. A bandage suspends the hanging cast from the neck and is inserted through a wire ring imbedded in the plaster immediately over the radial styloid. Speed,[3] LaFerté and Rosenbaum[4] and others have recommended this form of treatment in fractures of the shaft and upper third of the humerus, including the surgical neck. Treatment with the hanging cast does not immobilize the fracture site, but it is a means of applying continuous traction to the arm. In my experience this method has not worked satisfactorily in children (fig. 5) with fractures of the surgical neck, or in some adults who are uncooperative and seem to fail to understand the objective. The hanging cast technic undoubtedly has a place in the treatment of many fractures of the humerus, but it has been utilized in selected cases only and should not be recommended for general use as the method of reduction and immobilization.

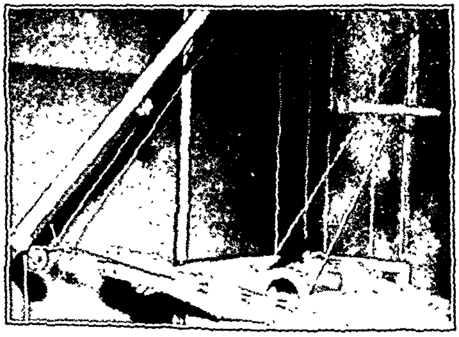

Fig. 4.—Photograph demonstrates the traction setup used frequently in the treatment of fractures of the humerus.

FRACTURE OF THE GREATER TUBEROSITY

Fractures of the greater tuberosity of the humerus are the result of a direct blow, due either to a fall on the shoulder or to avulsion of the tuberosity associated with dislocation of the humerus (fig. 6). Occasionally it is pulled loose by severe muscle pull. Watson-Jones claims that in nearly 30 per cent of dislocations of the shoulder there is a fracture of the greater tuberosity of the humerus. The patient is usually unable to rotate the arm outward. If there is no displacement of the fragment, the arm may be immobilized in a sling with a pad in the axilla; however, if the fragment is avulsed and the supraspinatus muscle becomes inactive because of its insertion into the bone, there is disability of the arm due to partial loss of abduction and external rotation. When a fracture of the greater tuberosity is associated with dislocation of the shoulder, the humerus should first be reduced with the patient under general anesthesia. Often the tuberosity will line up without further manipulation. Simple fracture of the tuberosity should be treated by attempted reduction. The arm is held in abduction and external

rotation by means of a plaster shoulder spica. However, operative intervention may be necessary in some cases to obtain satisfactory reduction.

EPIPHYSEAL SEPARATION (UPPER END)

In children and young adults, separation of the upper epiphysis is occasionally seen (fig. 7). The mechanism of production is similar to that for fracture through the surgical neck. It is important to remember that accurate reduction is desired in an effort to avoid any disturbance in growth of the humerus. The treatment consists of gentle manipulation with the patient under anesthesia, with maintenance of the reduction in a Thomas splint for a few weeks. This may be followed by the application of a plaster torso cast with the arm abducted to 45 degrees for a time. In some cases, however, immobilization of the arm in a sling is adequate.

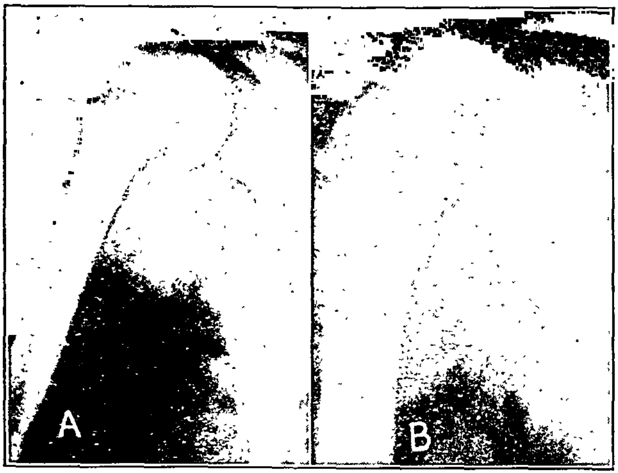

Fig. 7.—*A*, roentgenogram illustrating separation of the epiphysis of the upper end of the humerus. *B*, reduction after gentle manipulation and immobilization for a few weeks.

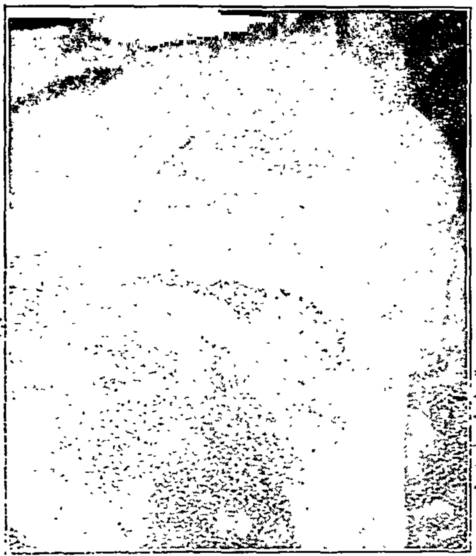

Fig. 8.—Roentgenogram of the upper end of the humerus showing fracture through a rarefied area in the bone. Patient was unaware of a bone cyst in the upper end of the humerus prior to injury.

FRACTURES OF THE SHAFT

Fractures of the shaft of the humerus are challenging to the physician because of the many problems which they present. The injuries of the shaft are often readily diagnosed because of the apparent deformity and loss of function. Miller has emphasized the importance of recognizing concomitant injury of the large vessels and nerves, especially the radial nerve. One should note in writing the "presence or absence of wrist drop, for, if this is first observed after reduction has been made, an embarrassing controversy may arise as to the cause of its production."[5] During delivery, particularly in breech or vertex presentations, the middle portion of the shaft is occasionally fractured. The proximal fragment is usually drawn outward by the pull of the deltoid muscle. Occasionally radial nerve palsy develops. The treatment of the fracture consists of reduction and simple immobilization of the entire arm in a posterior splint. With proper support, bone union is rapid in infants.

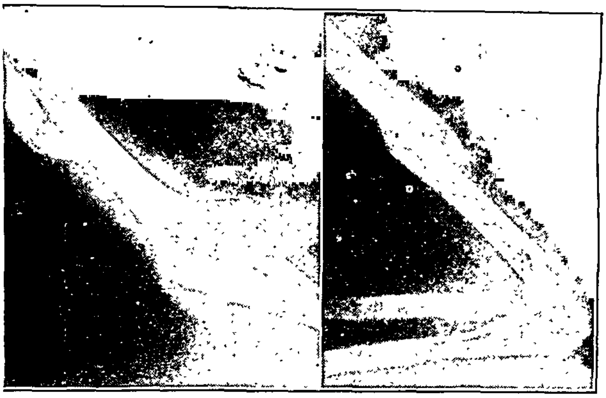

Fig. 9.—End result of treatment of fracture in the midhumerus in a young boy who sustained multiple fractures in an automobile accident.

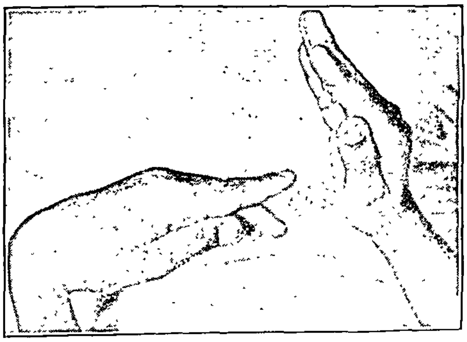

Fig. 10.—In this patient, a radial nerve palsy developed, with a wrist drop (left hand). Neurolysis resulted in normal function of the hand.

Certain pathological conditions as solitary bone cyst (fig. 8), Paget's disease, osteomyelitis, metastatic carcinoma and sarcoma may predispose the arm to the spontaneous fracture of the shaft of the humerus. The patient, unaware of the disease process in the bone, learns of the condition for the first time when his arm breaks without any obvious reason.

There is a possibility of delayed union or nonunion in fractures of the mid portion of the humerus. Factors contributing to nonunion are interposition of the soft parts, improper application of the cast, or injury to the an episodic, recurrent, central nervous system disorder rather than with the particular pattern of the seizures themselves, it does not seem urgent to digress at this point with a detailed description of seizure types, the major features of which are familiar to most practicing clinicians.

The general behavior that is to be presented as primarily symptomatic of epilepsy in children consists of a cluster of traits, which may be most adequately described in terms of its five component features. There is no single term that accurately describes the entire syndrome, and if there were it would not, for some time at least, be intelligible to parents and others from whom information must be secured as to the behavior of epileptic children in comparison with that of their nonepileptic siblings or companions. The presence of several, but not necessarily all five, traits contributes to the general pattern. No one or two of them alone are characteristic of *this or any other psychological disorder*. The five traits to be described more completely below appear to be (1) erratic variability in mood or behavior, (2) hypermotility, (3) irritability, (4) short and vaccilating attention span and (5) a rather selective difficulty in mathematics as a school subject.

The secondary symptoms, representing the child's reaction to his convulsive disorder and the way his handicap is regarded by his family and others in the community, being subject to more variables than the primary symptoms, do not fall into any such characteristic cluster. For some children the threat of being unexpectedly overwhelmed by a major seizure may inspire perennial dread or anxiety. For others, oversolicitude on the part of worried parents may hamper their activities and prove a source of irritation. For still others, exclusion from school and other community activities that are accepted as the birthright of youngsters in a democracy may provoke despair or resentment. This very variety in secondary reactions has led many students of epilepsy in childhood to conclude that there is never any specific behavior pattern for children subject to convulsions and that one must consider any apparent unusual reactions only in terms of psychological accompaniments of chronic illness.

THE PRIMARY BEHAVIOR DISTURBANCES

My opinion that there is a cluster of behavior traits that frequently occur in conjunction with epilepsy in childhood arose originally from my opportunity over a period of some years to compare the behavior of a great number of children with convulsive disorders and nonepileptic children sharing activities of a comprehensive program in a children's psychiatric hospital.[1] Concomitantly, information obtained in office practice while taking medical and psychiatric histories on children with convulsions, in which specific inquiry was made as to their behavior as compared to that of others in the family, led to similar conclusions. Moreover, there are many references in the literature that imply or directly suggest that others have made similar observations, though the reports may differ in terminology, emphasis and conclusions.

The five traits which were briefly enumerated above may now be described in more detail.

1. Erratic variability in mood and overt behavior implies an apparently unprecipitated, purposeless fluctuation in social adaptability occurring at longer or shorter, and usually irregular, intervals. The child who is old enough to express his own opinion of himself may speak of his "good and bad days." The mother may report that "for no good reason" on some mornings her child's disposition is conspicuously different from what it is on other days and go on to say that she knows from experience that it is likely that on certain days the child is going to have a difficult time. A teacher may observe that on some days or parts of days it seems to be much more difficult for a child to sit still in the classroom, to concentrate on his school work or to remember what he has learned previously. On such days he is often more irritable in his relationships with his classmates. Not only are the fluctuations in mood and behavior conspicuous, but also the lack of apparent external cause for them is particularly *puzzling and often frustrating to the child*, to his parents and to his teachers. This variability in disposition appears to be a basic characteristic of some epileptic children and very much colors and modifies the other behavior traits about to be discussed.

2. Hypermotility refers to gross motor activity, more extreme or more constant than is usually seen in other children of comparable age and development. The actual degree of hyperactivity may decrease as the child becomes older and maturer, but it still continues to be a conspicuous characteristic. There are many synonyms for such overactivity, such as excess energy, restlessness, drive, or "driveness."

3. Irritability (which is probably synonymous with irascibility) relates to the relative ease with which some persons become impatient, angry or aroused to aggressive, hostile, vindictive activity. It is so frequent a symptom in many sorts of emotional maladjustments that it would hardly be worthy of inclusion in the present category were it not for the degree with which it impresses many parents, teachers and other observers as being present in some epileptic children. It is, of course, also, of the several characteristics which we are discussing, one of the most likely to bring a child into conflict with his fellows. It seems to be subject to the variability that we have just discussed, and the fact that it occurs often without any relationship to the child's surroundings sometimes makes it difficult to understand.

4. Short attention span refers to a child's inability to concentrate, to apply himself continuously to a task or a matter of interest. Distractibility would be an equally appropriate term. In consideration of such a trait, due allowance must be made for the child's developmental level and the nature of whatever activity or task is supposed to be the focus of his attention at any particular time or in any particular situation. This characteristic is also subject to wide variations of the same unpredictable nature as those just discussed.

5. Selective difficulty with mathematics in the school situation is, of course, noted only in children whose school curriculum includes arithmetic. In older children the difficulty is most likely to be reported in situations calling for reasoning or problem solving, as contrasted

---

[1] The Emma Pendleton Bradley Home, East Providence, R. I.

with such tasks as merely memorizing tables or processes. In some children of superior intelligence the presence of a reading or spelling disability may mask the importance of the arithmetic problem.

Earlier Reports.—It is interesting, in the light of the observations which have led to the present contribution, to refer to a report by Clark in 1918,[2] who noted many of the same behavior traits in children with convulsive disorders. Over a period of many years this author presented a great deal of evidence attempting to demonstrate that convulsions occurred only in individuals of a very definite type of personality. In this particular study he carefully questioned the parents of 50 children subject to convulsions who were seen as private patients, and he recorded a number of personality traits occurring in a significant proportion of them which he considered to be related to the problem of epilepsy itself. Among these, he noted that "a factor most frequently noted in the supersensitive, egoistic infancies of these individuals was the extreme lability of mood, 'one moment contented, the next irritable beyond power of appeasement.' " Clark seems to be describing the quality of variability in these remarks. "In at least a dozen cases and as school pupils these potential epileptics were restless, turbulent, argumentative and quarrelsome in the extreme," describes hypermotility and irritability, the latter characteristic being one which Clark expands with such phrases as "the majority of cases show irritability from birth." He further noted that "two-fifths showed a marked inability to concentrate their attention, so that they were usually behind in several studies, such as algebra and mathematics," a statement which specifically refers to short attention span and difficulty in arithmetic, as mentioned above. He stressed the fact that he was concerned with children who were not mentally retarded, and in spite of his emphasis that the various characteristics that he delineated were earmarks of a very special personality, he noted considerable variation in attributes. Moreover, without the benefit of the many years of accumulated child guidance experience now available since he made his study, he failed to discriminate between symptoms that might be characteristic of the neurological disorder itself, as contrasted with those which are more indicative of the reaction of the child to his illness, the concern of his parents or problems of adjustment he faces in the community.

Electroencephalographic Evidence.—Numerous reports of electroencephalographic studies of maladjusted children contain descriptions of behavior of the type just described in association with electroencephalographic tracings similar to those seen in epileptic children. Jasper, Solomon and Bradley[3] in 1938 described a group of 30 children "whose behavior might be described as hyperactive, impulsive, highly variable and involving spontaneous misbehavior apparently unrelated to environmental situations," of whom 70 per cent showed electroencephalographic records judged to be epileptiform. Among several patients reported on by Lindsley and Bradley[4] were three whose electroencephalograms were of the convulsive type, who had actually suffered from seizures and for whom "the main complaint and major symptoms while in the hospital were primarily those of unacceptable behavior, such as hyperactivity, destructiveness, emotional outbursts and negativism." Strauss, Rahm and Barrera[5] reported the cases of a number of children who showed cortical dysrhythmias, who had been known to have seizures, and in some of whom symptoms included episodic temper outbursts showing a relatively normal type of behavior between outbursts. Others who report electroencephalographic studies and describe similar behavior characteristics in association with tracings of the epileptic type are Lindsley and Cutts,[6] Brown and Solomon,[7] Bradley,[8] and Jenkins and Pacella.[9] The general type of behavior described in several of these reports lends weight to my contention that there is a behavior syndrome apparently directly related to the neurophysiological disturbances that result in various types of seizures and that may be graphically recorded in the electroencephalogram.

In a recent discussion, Jasper[10] notes "the electroencephalogram has served to broaden the field of epilepsy to include many episodes of thought and behavior." He also adds "any portion of the brain occupied by epileptiform discharge is lost to the individual for normal adaptive or integrative action of that area." Since fluctuation and variability are characteristic of the abnormalities recorded in the epileptic type of electroencephalogram, we can sense a possible explanation of the variability in behavior and short attention span described as part of the syndrome considered as a primary behavior characteristic of epileptic children.

Similarity to Organic Behavior.—Many writers on epilepsy in childhood mention the fact that behavior difficulties, when present in this condition, often resemble those seen in patients with organic brain damage. The behavior referred to is apparently more or less the same syndrome under discussion in this section. Bender's[11] comprehensive review well summarizes the essential features. She speaks of "hyperkinesis which is not modifiable by psychotherapy" and refers to "organic driveness," a term first introduced by Kahn and Cohen[12] some years earlier. They describe it as a behavior syndrome, supposedly associated with brain stem damage and characterized by hyperkinesis, inability to maintain quiet attitudes, abruptness in movements and explosive release of motor activity. Among their case reports is that of a child who showed constant motion with pressure to speech, distractability and "unpredictable oddities in executing commission." Ewalt [13] comments on the similarity of this and other "organic behavior" to what is seen in epileptic children, illustrating his point with case reports. Strauss and Lehtinen [14] describe the brain-injured child as erratic, uncoordinated and uninhibited. Rosenfeld and Bradley [15] itemize the behavior of children of unimpaired intelligence who have suffered anoxia in infancy as being high lighted by "unpredictable variability in mood, hypermotility, compulsiveness, short attention span, fluctuant ability to recall material previously learned and conspicuous difficulty with arithmetic in school." Possibly the same throwing out of control of centers facilitating adaptive and integrating behavior described by Jasper [10] as related to the behavior of epileptic individuals also occurs as the result of brain damage. The similarities of behavior in epileptic children, even in the absence of objective evidence of brain damage, may be dependent on the same mechanism as that occurring in known brain-injured patients.

SECONDARY BEHAVIOR DISTURBANCES

The behavior that, because of its frequency and consistency in association with convulsive disorders, I have been discussing in terms of primary characteristics may not be conspicuous in some epileptic children. Moreover, these traits will probably seem most relevant to convulsive disorders to clinicians who have had opportunities to directly compare the behavior of epileptic and nonepileptic children living in the same environment or have focused on such behavior in taking clinical histories. They may not be equally apparent when studies are carried out from different viewpoints. In reports oriented largely from the psychologist's point of view, Gahagan and Sullivan,[16] Price, Kogan and Tompkins,[17] Lisansky [18] and Kogan [19] imply that epileptic children have no personal characteristics which distinguish them from other children of similar background and general capabilities. Lennox [20] and Bridge [21] in numerous contributions based on extensive clinical experience emphasize the fact that children who are the victims of chronic illness, particularly when its major symptoms occur dramatically and unpredictably, are likely to establish behavior patterns based on their personal reactions to their disorder and the way it is handled by those about them. I would suggest that such reactions be considered secondary to epilepsy, but they are certainly important for clinical consideration in every patient, whether or not the traits previously described are likewise conspicuous.

The physician who is genuinely concerned with his patient's welfare will always keep in mind the fact that all human beings have their own individual feelings and attitudes about their illness and also about the way other persons deal with them and their disorders. In the case of epileptic children these may be dread of seizures themselves, particularly if they are of major proportions or tend to occur while the child is in public places, from which repeated episodes may eventually result in his exclusion. In the case of other children, the parents, who must inevitably be concerned about seizures, regardless of the degree of their severity or crippling nature, may communicate their anxiety to the patient and thus aggravate whatever concern is already disturbing his emotional equilibrium. Unfortunately, public attitudes toward seizures and their victims are in many quarters unenlightened, and many epileptic children are being excluded from activities in which they could profitably engage. Such restrictions in some instances stimulate compensatory behavior reactions that may be a problem for the patient or his family. The possibility that certain anticonvulsive medications may, for some children, have an unfavorable effect on behavior must not be overlooked.

The reaction of children to these and other factors has been well summarized by Lennox [20] and by Bridge,[21] and the latter particularly has dealt with the general management of these problems in a comprehensive manner.

TREATMENT BY THE PHYSICIAN

The ultimate aim of treatment in any disorder is to restore the patient to as full participation in all desirable life activities as is consistent with his health. In the case of epilepsy, medical treatment aimed at control rather than cure of seizures is usually the first objective of most physicians. Since, however, therapy must usually be continued over long periods of time, it must not be pushed to such an extent that, as the result of whatever regimen is employed, the child is denied a reasonably full participation in all those activities that at successive developmental stages are essential to his physical, intellectual and emotional growth. It is not my intention to critically evaluate any of the accepted medical programs designed to eliminate the major symptoms of seizures. I would like, however, to point out that large doses of sedative drugs may seriously interfere with effectual mental functions, and that too drastic restrictions of diet or activity may set a child too far apart from the stimulating companionship of his fellows and the benefits of a full educational program. Moreover, the physician, in his own anxiety to be thorough both diagnostically and therapeutically, may by his manner of handling the situation engender more anxiety than reassurance in both parents and children. Supervising adequate treatment of an illness that has for centuries been dreaded because it has been poorly understood is an art that calls for the physician's reassurance and enthusiastic support of the grow-

ing child, quite as much as it does for his protection. An awareness of and willingness to deal with both the primary and secondary behavior characteristics of the patient is an important portion of the physician's responsibility, if the child's seizures are to be controlled at the same time that he is participating in as full a program of normal childhood activities as is possible.

Treatment of Primary Behavior Disturbances.—If the cluster of symptoms referred to above constitute a handicap to successful school or community life, they must be one object of treatment. Since these symptoms presumably are the result of neurophysiological disturbances of the same general nature that also produce seizures, they will not, aside from their recognition and acceptance as such, yield to psychotherapeutic measures alone and must be dealt with medically. The literature on their pharmacologic control is recent but encouraging. It is interesting that little mention is made of the effect of the older drugs, particularly bromides and phenobarbital, on behavior, except to indicate that overdosage will aggravate behavior difficulties, primarily by dulling sensibilities and temporarily retarding effective intellectual function. In my experience, based on innumerable reports from parents and nurses who are in daily intimate contact with epileptic children, phenobarbital, even in average nonsedative doses, results in increased irritability and hyperactivity and, at times, interferes with effectual ability to concentrate attention upon specific tasks, such as school work. The interesting and convincing study of Lindsley and Henry [22] bears this out. They found that when the effect of conventional therapeutic doses of phenobarbital on behavior was compared under controlled conditions with that of other drugs commonly used in children with convulsive disorders, it resulted in less satisfactory adjustment than when no medication was given.

After the introduction of diphenylhydantoin (dilantin®) sodium into clinical practice, a number of observers noted that it frequently had a favorable effect on behavior, even when seizures themselves were not a major problem. The reports of Putnam and Merritt,[23] Solomon,[24] Brown and Solomon,[7] Bradley [8] and Brill and Walker,[25] among others, present evidence of this nature. The major effects were those of decreased irritability, control of hypermotility and occasional decrease in the variability of behavior noted above as primary symptoms. Other anticonvulsive drugs reported as having similar beneficial effect on children with seizures, or those whose electroencephalograms were of the "epileptic" type, are trimethadione (tridione®) reported by Perlstein and Andelman,[26] methylphenylethyl hydantoin (mesantoin®) as noted by Tietz [27] and phenacetylurea ("phenurone") studied by Livingston and Kadji.[28]

In my experience, borne out by the controlled studies of Lindsley and Henry,[22] the most effective preparations for the control of the primary behavior disturbances have been the amphetamines, notably racemic amphetamine (benzedrine®) sulfate and its dextrorotatory isomer known commercially as dexedrine® sulfate. These have been extensively reported in a recent article,[29] in which benzedrine® was found to be more efficient than dexedrine® in epileptic children. These preparations in rather full adult doses (10 to 20 mg. daily in the morning) even in younger children often dramatically reduce the variable swings of mood and activity so frequently seen as part of the primary behavior disturbance. They may also increase attention span, with resulting favorable effect for older children in arithmetic achievement. Since these drugs are central nervous system stimulants, and with the exception of isolated reports have not been notably effective in the control of seizures themselves, it is thought that their favorable effect on behavior is associated with their known stimulation of mood, possibly rendering variations in sensitivity and irritability less disturbing to the patient. The amphetamines may always be used, when indicated, in conjunction with conventional anticonvulsive medical regimens, their major drawback being their inhibition of appetite for food. Occasionally, when large doses of sedative drugs are employed, their stimulating action may neutralize annoying soporific effects, as illustrated in one of Bradley's case reports.[30]

Treatment of Secondary Symptoms.—Secondary symptoms, representing the child's reaction to his illness and the emotional atmosphere in which he finds himself, are proper material for psychotherapeutic measures. The essentials of their effectual handling have been suggested repeatedly above. These may be summarized by advocating control of seizures without overdosage with sedative drugs, helping the child and his parents understand and realistically accept his illness with a minimum of crippling emotional overtones and assuring the patient of as full and free a program of all usual childhood activities as possible. Frequently this full program in school and in the community will require that the physician contribute to the enlightenment of school personnel as to the nature of the child's illness, its harmlessness as far as other children (and their parents) are concerned and the contribution to the patient's total welfare, development and happiness that acceptance into community activities assures. Information about epilepsy is available to lay readers through such organizations as the National Epilepsy League, and the informative volumes by Lennox [31] and Putnam [32] are enthusiastically recommended.

CONCLUSION

Convulsions and their accompanying behavior disturbances are still a problem for many children. However, our increasing understanding of the basis of epilepsy through modern advances in neurophysiological techniques and our potential ability to control and eliminate seizures themselves through the many new therapeutic agents that have become available in recent years should give us confidence in the medical management of these disorders. If, in addition, the feelings and behavior of epileptic children may be considered and constructively handled as has been suggested, there is ample cause for optimism. The well informed and alert pediatrician or family physician may well impart this to those who share with him the responsibility for epileptic children.

SUMMARY

Children who are subject to convulsions may have behavior difficulties of two general sorts. There are often behavior symptoms that are the primary, direct result of the neurophysiological disturbances that may be recorded electroencephalographically, and that are also presumably directly related to the seizures themselves. Such behavior symptoms are best treated medically, the most effectual preparations at present available for this purpose being the amphetamines. Other behavior disturbances, representing the child's reaction to being ill and to the way he is handled by those about him, may be considered as secondary symptoms; these are less specific in nature and must be treated at the psychological level. Adequate medical management of the epileptic child involves consideration of his behavior and emotional reactions, in addition to therapy designed to control his seizures.

ABSTRACT OF DISCUSSION

Dr. William W. Belford, San Diego, Calif.: The facts presented are the results of over 15 years of study and work with the problems of children subject to convulsions and the problems of their parents and environment. Many drugs and forms of treatment are presented each year, but few are so well studied and tried out and proved by use. Often the school teachers and nurses need instruction and encouragement in the care of these children such as only physicians can give them. A visit with them does both the physician and the child much good and can iron out much friction and misunderstanding. More time spent with the parents in encouraging and explaining the problems to them is just as helpful as the drugs that we prescribe. The burden of epilepsy is far greater than just drug treatment and the daily problems of living. Let me urge that the diagnosis of epilepsy be made with great care. It is so hard to correct a mistaken diagnosis once it is put on a child. Those of you who deal with children and adults through their lives are quite aware of the tag of epilepsy that prevents someone just out of school or a young adult from getting a job.

Dr. E. D. Anderson, Minneapolis: With the advance in knowledge of the diagnosis, prognosis, and treatment of epilepsy, and with a better understanding of the psychological problems of the epileptic and his family and the effect that they can have upon the course of the disease, the medical profession is assuming a more positive and hopeful attitude. Unfortunately, many of us still confine our treatment to the giving of drugs, and neglect the equally important part of therapy which Dr. Bradley presented; namely, the prevention and treatment of the emotional and behavior difficulties which these children so frequently have. In my experience, the biggest factor in helping the epileptic child to adjust to his illness is the understanding and attitude of the parents to the disease and to their child. Unless they can be helped to understand their own emotional problems connected with the illness, it is almost impossible to help the child. One of the most common and damaging emotional problems that occurs in these parents is a feeling of defeatism. When the parents have this attitude, the child is almost bound to develop the same feeling. It is wrong not to give the encouragement of hope which our present prognosis of treatment gives us the right to do. Many parents develop feelings of anxiety regarding the physical welfare of their child because of the seizures and momentary lapses of consciousness he has and the danger of injury in traffic and at play. Unless the parents are given proper guidance, they are likely to restrict the child's activities far beyond what is necessary. We must try to help them see that it is necessary to take certain chances in order that the child may lead as near normal a life as is possible. Not to do so will invariably lead to emotional trauma, with resulting behavior and personality problems. Another common form of anxiety which the parents have is the fear that their child will deteriorate mentally. As a result, they may do one of two things. To reassure themselves that the youngster is bright, they constantly push him far beyond his capacity to excel in school. Thus, he may become frustrated, discouraged, or resentful. Other parents, instead of pushing, hold him back. They make all decisions and do everything for the child, thereby preventing him from becoming independent. Some parents have feelings of guilt regarding the child's illness. Whatever the cause of the feelings of guilt, the parent is likely to be overly protective and indulgent and the child becomes overdependent, with resulting increased emotional and behavior problems. Frequently parents of an epileptic child develop feelings of shame regarding the illness. Such parents have a tendency to withdraw from normal social, community and civic activities. They particularly need the help which such activities will give. If you and I do nothing but help such parents to see that epilepsy should not be considered a thing of shame and help them to keep interested and active in the normal activities of life, we will have done a great deal. One or more of such problems are almost bound to arise in the parents of epileptic children. If they are not prevented or controlled, the parents are going to become emotionally insecure and unstable, and they will be unable to adequately help their child meet the difficult problems which will face him. Physicians are in a strategic position to help these parents by giving them warm understanding and wise counsel and guidance.

Dr. Charles Bradley, Portland, Ore.: I do not know how many children who are subject to seizures have behavior difficulties, particularly those five cardinal traits that we mentioned. My guess would be one-half to two-thirds. There are just enough children who do not have problems of that sort, to make it possible for many of us to say that there is no characteristic behavior of the epileptic child. There are no persons in relation to the young child who are as important to him as his own parents; their support and enthusiasm are even more important than that of the family doctor. If we have the confidence of the parents and a reasonable acquaintance with some of these things, we can offer our patients more assurance and encouragement, and engender less anxiety in them and the parents than has been the case in the past.

Occiput Posterior.—At present there is general agreement among students of the problem of the occiput posterior position insofar as most of the practical aspects are concerned. It is a normal, frequently occurring position and radical interference with it is no longer justified. With competent handling of the occiput posterior, the safety of mother and baby is quite comparable to that obtained with other positions. . . . The rule of the clinic at the University of Minnesota may be quickly stated. Occiput posteriors are left alone unless a specific indication for interference presents itself. The usual indication is lack of progress with the head at the outlet. If the head can be easily rotated with the hand, this is done and the patient is given further opportunity to deliver spontaneously. If it can be gently rotated with only the fingers of one hand on the forceps, this is done. If any resistance to rotation is encountered, delivery is carried out as a posterior and usually after deep episiotomy.—John L. McKelvey, M.D., and Eugene J. Diefenbach, M.D., The Obstetric Significance of the Posterior Occiput Position, *Postgraduate Medicine,* March 1951.

OBSERVATIONS ON ACUTE POLIOMYELITIS WITH RESPIRATORY INSUFFICIENCY

Fred Plum, M.D.
and
Harold G. Wolff, M.D., New York

In a series of 50 adult patients with acute poliomyelitis managed at the New York Hospital in 1949, 17 needed artificial respiration. Of these 17, nine had respiratory obstruction due to partial or complete paralysis of swallowing or coughing. The respiratory exchange of oxygen and carbon dioxide was intensively studied in this entire group of patients. The effects of the rapid rocking bed, the cuirass respirator and the tank respirator were ascertained on those in whom respiratory decompensation developed. In this preliminary communication some of the observations are reported.

These patients were a severely ill group, many of whom were referred to the New York Hospital because of the desperate nature of their illness. Eight of the 17 died of rapidly progressive poliomyelitis, which both involved the innervation of the peripheral respiratory apparatus and extensively destroyed brain stem centers. Death was due either to circulatory collapse, apparently the result of involvement of the medullary reticular substance by the virus, or to the effects of hypoxia and hypercapnia accompanying respiratory failure.

OBSERVATIONS ON CIRCULATORY AND RESPIRATORY FAILURE

Baker and associates[1] have shown that cardiovascular signs and symptoms are consistently associated with severe damage to more than 19 per cent of the large reticular cells of the medulla. In our experience, arrhythmias and shock due to failure of neurogenic cardiovascular regulation proved unresponsive to therapeutic measures, such as administration of the digitalis glycosides or phenylephrine (neo-synephrine®) and parenteral injection of fluids.

In contrast to the discouraging prognosis offered by circulatory failure, the ill effects of respiratory insufficiency could often be prevented or reversed, and therefore the maintenance of a physiologic respiratory exchange was given primary attention.

Effects of Hypoxia and Hypercapnia.—In dealing with poliomyelitis, the importance of avoiding hypoxia and the dangers attendant on the hypoxic state have in general received greater emphasis than have the incidence and sequelae of carbon dioxide retention. Hypoxia results in increased capillary permeability,[2] pulmonary edema,[3] cardiovascular collapse[4] and damage to the central nervous system.[5] High levels of carbon dioxide in the blood (hypercapnia) result from inadequate alveolar elimination of the gas and if not reduced lead to blood acidosis, headache, hypertension,[6] disorientation and loss of consciousness.[7] Hypercapnia may also depress the respiratory center[8] and cause vascular collapse.[9] Nearly all these effects of hypoxia or hypercapnia may further interfere with respiratory gas exchange or intensify the severity of an acute illness. The prevention or reversal of even borderline respiratory decompensation is thus of first importance in managing patients with acute poliomyelitis.

Evaluation of Respiratory Insufficiency.—In evaluating the oxygenation of these patients with acute poliomyelitis, both the efficiency of respiratory gas exchange and the ability to move air in and out of the lungs were repeatedly ascertained. Arterial oxygenation was followed by studies with the oximeter (which photoelectrically measures oxyhemoglobin content),[10] and these determinations were standardized by direct arterial blood gas analysis. Carbon dioxide exchange was evaluated by frequent determinations of venous plasma carbon dioxide-combining powers and periodic estimations of arterial carbon dioxide contents. Alveolar air samples were also analyzed. Vital capacity was measured with a waterless calorimetric spirometer.

Marked failure of adequate elimination of carbon dioxide occurred in at least four well oxygenated patients in the present group. These patients, all of whom were receiving oxygen therapy, maintained arterial oxygen saturations of 95 to 100 per cent despite venous plasma carbon dioxide-combining powers of 85 to 100 volumes per cent and similarly elevated arterial carbon dioxide contents. They suffered headache, hypertension and disorientation during the time of increased blood carbon dioxide levels, and these symptoms were reversed in three by increasing ventilation and eliminating the accumulated carbon dioxide.

Measurement of Vital Capacity.—Observations on acutely ill adult patients indicated that no significant threat to adequate gas exchange existed until the vital capacity fell to 1,000 or 1,200 cc., since the patients studied consistently maintained physiologic levels of their respiratory gases when their vital capacities exceeded this

amount. When 1,000 to 1,200 cc. was reached, however, arterial oxygen saturations and venous plasma carbon dioxide-combining powers were more closely followed, since it was observed that when the patient's paralysis was still progressing respiratory decompensation frequently appeared shortly after this point. Studies with the spirometer[11] on a group of adult respirator patients convalescing from poliomyelitis demonstrated that they were consistently able to meet their breathing requirement without any artificial respiration or supplementary oxygen when their vital capacities climbed to the low level of 600 to 700 cc. However, their breathing requirements were less than those of acutely ill patients, in whom infection, fever and anxiety increased metabolic demands, so that a direct correlation could not be made between these figures and the need for a respirator in acute ventilatory insufficiency.

Detection of Hypoxia.—Since cyanosis may not be present until arterial oxygen saturations fall to 80 per cent or less,[12] the oxygen content of arterial blood determined either by blood gas analysis or the oximeter provided the only reliable index of low grade hypoxia. With the patient breathing 100 per cent oxygen for at least five minutes, arterial blood was withdrawn for analysis and the oximeter placed on the ear. The oximeter was thus standardized to the patient's degree of oxygen saturation at that time, and future changes in oxygen saturation could be immediately and accurately determined. A drop of more than 5 to 8 per cent in the arterial oxygen saturation when the patient was changed from inhaling 100 per cent oxygen to breathing room air was taken to signify anoxemia.[13] When a patient breathing room air had an oxygen saturation of 94 per cent or less, oxygen therapy was always instituted. Most patients, of course, received oxygen therapy before this degree of anoxemia occurred. Oxygen was delivered at a rate of 4 to 8 liters a minute by nasal catheter. By the use of the oximeter to complement direct arterial blood gas analysis, continuous accurate evaluation of oxygenation was possible. The need for many technically difficult and time-consuming direct blood studies was eliminated.

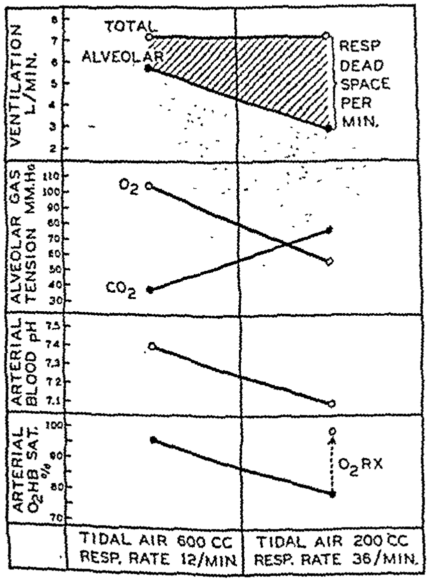

Chart 1.—Mechanism of alveolar carbon dioxide accumulation and blood acidosis in reduced alveolar ventilation. Despite the fact that total ventilation remains constant, alveolar ventilation falls sharply as tidal air decreases and the respiratory rate increases. Carbon dioxide, as a result, is *not eliminated*, and the blood pH shifts to a more acid level. Oxygen therapy corrects anoxemia but does not appreciably affect the accummulation of carbon dioxide.

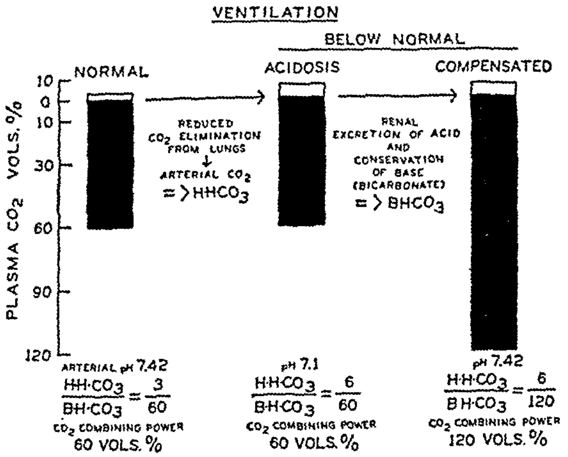

Chart 2.—Mechanism of blood acidosis in carbon dioxide retention, and development of a high venous plasma carbon dioxide-combining power in renal compensation of respiratory acidosis. Increased alveolar carbon dioxide is equal to increased arterial $H.H.CO_3$ (carbonic acid), and the arterial pH falls to 7.1. As the venous plasma carbon dioxide-combining power rises, owing to renal conservation of base, the arterial pH returns to the normal value of 7.42.

Detection of Carbon Dioxide Retention and Its Significance.—The mechanism of carbon dioxide retention in these patients with ventilatory reduction and the effects of this retention on blood pH are diagrammed in chart 1, which hypothetically outlines the course in one of the patients studied. The respiratory dead space (approximately 150 cc.) had to be filled on each inspiration before any fresh gas reached the alveoli, and the dead space remained essentially the same, even though tidal volumes diminished. Therefore, when tidal volumes fell, practically the entire reduction in the amount of air breathed was at the expense of alveolar ventilation. When, as in the example cited in chart 1, tidal volume fell from 600 to 200 cc., the entire 400 cc. of each breath was lost to alveolar gas exchange, and only 50 cc. (i. e., 200 cc. tidal volume minus 150 cc. dead space) of inspired gas flushed the alveoli.

As alveolar ventilation was reduced, oxygen tension fell and carbon dioxide tension rose in the alveoli and therefore in arterial blood. Carbon dioxide, because of its greater molecular weight, diffuses less rapidly than oxygen. Thus, although oxygen therapy raised the alveolar oxygen tension and arterial oxygen saturation to normal levels by replacing inert nitrogen in inspired air, carbon dioxide could be eliminated only by increasing tidal volume or excessively increasing the respiratory rate, thereby increasing alveolar emptying. Since the pH of the blood is dependent largely upon the equilibrium established between free carbonic acid (H_2CO_3) and combined carbonic acid ($BH.CO_3$), as the carbon dioxide retained was converted to carbonic acid, the blood pH shifted to a more acid level (chart 2). This shift in blood pH occurred simultaneously with carbon dioxide retention.

Med. 81:649 (May) 1948.

The plasma carbon dioxide-combining power, reflecting, as it does, available base, largely in the form of bicarbonate, for combination with carbonic acid, rose above its normal level of 60 volumes per cent as the kidneys excreted other acid salts and conserved bicarbonate. Thus, in contrast to the usual metabolic acidosis, where carbon dioxide is blown off by the lungs and the carbon dioxide-combining power falls, in the respiratory acidosis due to inadequate carbon dioxide elimination from which these patients suffered the carbon dioxide-combining power was high. Electrolyte acidosis, marked by a high carbon dioxide-combining power and a highly acid pH of the urine, is peculiar to states of reduced ventilation; and since renal compensation is a relatively slow process, blood acidosis persists until the ratio of free carbonic acid to combined carbonic acid is restored at 20:1. This may take several days.

Carbon dioxide-combining powers and urinary pH values were, therefore, followed closely in all patients suspected of ventilatory insufficiency. Arterial carbon dioxide contents were periodically ascertained to determine the exact status of carbon dioxide respiration.

OBSERVATIONS ON USE OF RESPIRATORS

If borderline hypoxia (arterial oxyhemoglobin saturations of 94 per cent or less) or progressive carbon dioxide retention, reflected by venous plasma carbon dioxide-combining powers exceeding 70 per cent, could not be overcome by eliminating respiratory obstruction through suction or tracheotomy,[14] artificial respiration was instituted. In patients with relatively slowly progressing poliomyelitis, small degrees of failure of carbon dioxide elimination, with carbon dioxide-combining powers rising to 65 or 70 per cent, occurred as much as 24 to 36 hours before respiratory insufficiency was severe and could be corrected by increasing ventilation for a few hours with a respirator. It was noted that certain patients who initially had difficulty synchronizing with a respirator and were irrational when first placed in one of these devices became rational and more cooperative when their blood carbon dioxide content returned toward normal.

The Rapid Rocking Bed.—The Fast Rocking Bed [15] had both the rate and the depth of its oscillations controlled and was useful in providing rest periods for five acutely ill patients whose unassisted breathing required maximum effort. By intermittently applying the weight of the viscera to the diaphragm at rates up to 24 per minute, and moving through an arc up to 20 degrees from the horizontal, the bed supplemented reduced breathing and helped maintain gas exchange by creating a bellows action on the thorax. It proved inadequate for continuously ventilating patients with drastically paralyzed respiratory musculature during the acute phase of poliomyelitis. In five accutely ill patients it delayed the need for a respirator several hours and enabled them to come out of the respirator sooner. Use of the rocking bed for more than a few hours at a time during the acute illness was limited to a certain extent by the fact that patients sometimes became nauseated and the constant motion interfered with sleep. The rapid rocking bed proved most valuable and was used most extensively during the period of convalescence from poliomyelitis.[11] During this period its action enabled nine patients with severely paralyzed respiratory musculature and vital capacities as low as 200 to 300 cc. to stay outside negative pressure respirators for many hours. The rapid rocking bed was an aid in weaning patients from respirators and enabled them to receive physical therapy and other treatments early in the course of convalescence.

The Cuirass Respirator.—For at least some patients the type of cuirass respirator studied [16] was safe for only brief periods at a time during the acute stage of respiratory insufficiency.[17] Two acutely ill patients were unable to correct severe carbon dioxide retention and acidosis while in this respirator. The carbon dioxide was eventually eliminated by increasing ventilation with a tank type respirator. Spirometer collections on one of these patients, as well as determinations on three convalescent and control subjects, revealed tidal volumes of only 230 to 410 cc., with negative cuirass respirator pressures up to 20 mm. of mercury. The lower volumes were found for the acutely ill subjects. Despite the failure of elimination of carbon dioxide, the arterial oxygenation, at least for a time, remained above 95 per cent in the two acutely ill patients in the cuirass respirator, and this initially obscured the respiratory decompensation.

Autopsies on three patients for whom the cuirass respirator had been used for periods of four to 24 hours preceding death, revealed moderately severe anterior pulmonary emphysema in all.[17] Studies of lung volume, performed during the eighth month of convalescence, on a fourth patient who had been treated in the cuirass respirator for a month during his acute illness, also revealed the presence of moderately severe pulmonary emphysema.[18]

Tank Type Respirators.—These devices [19] accomplished sufficient ventilation in all the patients studied to achieve adequate oxygenation and carbon dioxide elimination. Negative respirator pressures of 15 cm. of water accomplished effective ventilation in most cases, and physiologically effective tidal volumes of 480 to 720 cc. were observed in five patients studied in these respirators. Other investigators, however, have found that positive pressure breathing, synchronous with negative intratank pressures, must be added to the upper airway to achieve adequate ventilation and correct acidosis in some of their patients with respiratory paralysis.[20]

Subsequent observations on lung volume and pulmonary function in eight patients treated with the tank respirator have demonstrated that use of the latter was not associated with the severe degree of pulmonary emphysema found in patients treated with the cuirass type.[18]

The tank type respirator, therefore, was found to be the most satisfactory and the safest device available for combating severe insufficiency of breathing, and when its use is combined with positive pressure breathing the ventilation may be even more effective.

SUMMARY

In cases of acute poliomyelitis with ventilatory failure when vital capacities in adults fell below 1,200 cc., repeated venous plasma carbon dioxide-combining powers and arterial blood oxygen saturations were ascertained. In the absence of obstruction, if the venous plasma carbon dioxide-combining power progressively rose above 60 volumes per cent or the arterial oxyhemoglobin content fell below 94 per cent, the respirator was necessary to restore physiologic respiratory gas exchange.

Failure of carbon dioxide elimination by the lungs and increased levels of carbon dioxide in the blood (hypercapnia) were associated with respiratory paralysis in at least four patients who, as shown by arterial blood gas analysis, had oxyhemoglobin saturations of over 95 per cent. Carbon dioxide retention was reflected by rising venous plasma carbon dioxide-combining power with a normal or acid pH of the blood and acid urine. Accumulation of carbon dioxide in the blood, when not corrected by increasing alveolar ventilation, resulted in blood acidosis, was associated with hypertension and narcosis and may have caused cardiovascular collapse.

The tank type respirator achieved physiologically effective ventilation in patients with severely paralyzed breathing mechanisms. The cuirass type portable respirator could not be relied upon to maintain physiologic respiratory exchange. The rapid rocking bed was useful in supplementing respiratory efforts in patients with limited breathing ability.

ABSTRACT OF DISCUSSION

DR. JOE R. BROWN, Rochester, Minn.: The possibility that the retention of carbon dioxide might be of importance in the care of poliomyelitis was mentioned by Pitt at the International Congress on Poliomyelitis in New York. The reverse of this condition was observed at the University of Minnesota Hospitals in the 1946 epidemic, in which some of the tank type respirators produced excessive ventilation, blowing off excessive carbon dioxide and resulting in chemical changes in the blood which were the reverse of those observed by Drs. Plum and Wolff. It is important, therefore, to know that one is getting the correct amount of respiratory exchange, and not just that one has the respirator turned on at the settings which have been approved by the manufacturers. It would appear that both overventilation and underventilation will produce chemical changes within the blood which are deleterious to the patient. The problem of care of patients with poliomyelitis becomes complicated at times, and one hesitates to make any over-all statement. However, it is possible to clarify some of the observations which may be made. One may see inadequate gaseous exchange associated with deficiency of ventilation or deficiency of the alveoli of the lungs. Deficiencies in ventilation are due to paralysis of the diaphragm or intercostal muscles, depression or destruction of the respiratory center in the medulla or obstruction of the upper airway resulting from pharyngeal or laryngeal paralysis. Alveolar deficiency may be the result of pulmonary edema, atelectasis or pneumonia. Patients have to be watched closely for all these factors, and many factors are interdependent. An example is pulmonary edema caused by an obstructed airway. On the other hand, pulmonary edema itself will further obstruct the airway, producing a vicious cycle. In clinical observation of the patient, it is important first to realize that hypoxia alone will usually produce euphoria. This has been observed repeatedly under various experimental conditions in the air forces. However, retention of carbon dioxide produces a different clinical picture. Retention of smaller amounts of carbon dioxide has a stimulating effect; it produces anxiety, restlessness, fearfulness and, many times, a fear of death. If the patient is able to breathe, there will be an increase in the respiratory rate. As retention of carbon dioxide progresses, a depressant effect occurs, leading to a clouded mental state, delirium and coma. Initially there is an increase in the pulse rate and blood pressure, and finally there will be a state of shock. In many patients with poliomyelitis, retention of carbon dioxide is complicated by inadequate oxygenation. In retention of carbon dioxide the administration of oxygen may lead to temporary apnea. This results from removal of the stimulating effect of hypoxia on the respiratory center in the presence of the sedative effect of carbon dioxide. In subacute retention of carbon dioxide the compensated states occur which have been documented so ably by the authors. With hyperventilation the respiratory center itself will adjust to lower quantities of carbon dioxide in the blood, so that the new levels of carbon dioxide will then become the usual and accustomed levels. When such a patient is taken out of the respirator, he will have difficulty in adjusting because he is now accustomed to lower concentrations of carbon dioxide. It may be that with prolonged retention of carbon dioxide partial readjustment of the respiratory center as well will occur.

DR. ROLAND P. MACKAY, Chicago: This paper illustrates well the role which, ideally, should be played by clinical physiology in sharpening our management of neurological cases. It also emphasizes the extent to which the modern neurologist must acquaint himself with physiologic processes which are not usually considered relevant to clinical neurology. The conclusions of Dr. Plum and Dr. Wolff are illuminating. Elevation of arterial carbon dioxide may be instrumental in keeping the patient in delirium or coma, thus prejudicing his changes for survival at a time when oxygen studies suggest that he is in little respiratory difficulty. Since carbon dioxide is the most powerful stimulant of the respiratory center, its excess in the blood makes certain that a patient with bulbar poliomyelitis, whose respiratory center is already damaged by the disease, will be stimulated far beyond the capacity to respond. This is comparable to requiring a patient with a nearly paralyzed leg to exercise violently during the acute stage of the disease. The authors' experience of the great superiority of the tank respirator over the cuirass type accords with my own. The difficulty with patients with acute respiratory insufficiency is primarily a mechanical one and results from the failure of the diaphragm to perform its function and from the failure of the intercostal muscles of respiration. Therefore, it is certainly inadequate to put such a patient in an oxygen tent or to administer oxygen by any other means. The patient is damaged, actually, by carbon dioxide. In many hospitals, careful studies of the type presented in this paper are not possible, laboratory facilities not being at hand. A few simple clinical points may be of help in the management of the patient. One should remember the old clinical Litten sign for the detection of diaphragmatic excursion. If, in a darkened room, a light falls tangentially along the line of the chest, the excursions of the diaphragm may be observed in the indrawing of intercostal spaces. If the diaphragm is paralyzed, the fact may be detected in this fashion, as well as by the paradoxical infalling of the abdominal wall during inspiration. If a patient's carbon dioxide level is high, he will nearly always show some degree of cyanosis. Therefore close attention to the degree of cyanosis present will be of great help. Even small degrees of cyanosis can readily be detected in the lips and other tissues. On the other hand, if a patient in the tank respirator is hyperventilated, alkalosis may develop. In such cases, cyanosis likewise appears. But in a patient not in a respirator any degree of cyanosis is a danger signal and should call for the use of a respirator.

---

[20] Bennett, V. R.: Personal communication to the authors.

Dr. Fred Plum, New York: With reference to Dr. Brown's comments on hyperventilation in patients in respirators, I am curious as to whether the hyperventilation he observed was early in the stage of paralysis or later, in the stage of convalescence. Our experience was that hyperventilation was encountered in respirator patients only after they had passed through the acute, prostrating stage of poliomyelitis and were well into convalescence. Mr. Ray Bennett, the respiratory engineer, tells me that this experience was corroborated on a large scale by Dr. Bauer's group in Los Angeles, who encountered fairly severe respiratory acidosis even in patients in tank respirators but did not observe the hyperventilation syndrome except in convalescents. As to the mechanism of action of carbon dioxide on the respiratory center, carbon dioxide is usually used in stimulating amounts of about 5 per cent carbon dioxide to 95 per cent oxygen. If the carbon dioxide concentration is raised to about 10 per cent and the patient or experimental animal continues to breathe this mixture, the respiratory center becomes depressed. A similar phenomenon is present in the patient with pulmonary emphysema, who has chronic carbon dioxide retention. It thus appears that the respiratory center is probably depressed by high carbon dioxide tensions, rather than being exhaustively stimulated by them. In any case, only the carotid bodies provide chemical stimulation of respiration after the respiratory center is gone, and they are stimulated by hypoxemia rather than by high carbon dioxide tensions. The simple tests and the clinical signs which manifest hypoxia and hypercapnia are certainly of the greatest importance. However, we tend to feel that cyanosis cannot be relied on. Dr. Comroe, of Philadelphia, demonstrated the unreliability of cyanosis in the detection of hypoxia. He had a group of clinicians judge patients' arterial oxygen saturations by the degree of cyanosis present and checked these estimations with the oximeter. The correlation was poor, and anoxemia was not consistently manifested by cyanosis until arterial oxygen saturation fell to about 80 per cent. Dr. Brown's co-workers at the University of Minnesota extended studies of this nature to patients with poliomyelitis and by the use of the oximeter demonstrated that the presence or absence of cyanosis was not an accurate index of a patient's oxygenation. The carbon dioxide-consuming power of the blood is simply determined, as is the pH of the urine. Since frequently respiratory decompensation takes 24 to 48 hours to develop, a rising carbon dioxide-combining power and an acid urine would indicate that a patient with respiratory paralysis was not throwing off carbon dioxide and would guide respirator therapy.

ANESTHESIA FOR COMMISSUROTOMY FOR MITRAL STENOSIS

PRELIMINARY REPORT

Kenneth K. Keown, M.D., D. Dwight Grove, M.D.
and
Henry S. Ruth, M.D., Philadelphia

Gibbon,[1] in defining cardiac surgery made the following statements: "Operations upon the human heart have been confined chiefly to the surface or to the walls of the heart. The field of intracardiac surgery on human patients is in its infancy." Because of the increasing employment of intracardiac surgery in human patients, for which our department has been responsible for anesthesia, and because of the increasingly beneficial results obtained by such surgical procedures, it appeared to us that intracardiac surgery held such definite prospects for certain incapacitated patients that its application would increase. Therefore, it was thought that a report on the current methods of anesthetic practices employed by us might be helpful to others who may be called on for this application of anesthesia. This discussion will be limited to anesthesia for commissurotomies in cases of mitral stenosis. Of all surgical procedures on the mitral valve this one has produced the greatest benefit to patients in the hands of our thoracic surgery group.[2] It is possible that intracardiac surgical procedures of other types may be employed more frequently in the future. The current practices of anesthesia may well continue to be satisfactory for all intracardiac operations on adults, but we wish to emphasize that this is a preliminary report. The principles and methods described are the most satisfactory to date for mitral commissurotomies, but we will continue to seek any factor that may show possibilities of increased benefit.

PATHOLOGY OF MITRAL STENOSIS

It has been estimated that from 0.5 to 1.0 per cent of the community is affected where rheumatic fever is endemic, and 85 per cent of these by chronic valvular heart disease.[3] This statement provides the reason for the initial investigation of the effects of surgery on the mitral valve (the valve most frequently involved by the disease). Deformity of the mitral valve may result in major stenotic or regurgitant effects. Once these situations arise, the prognosis is unfavorable in almost every instance. Therefore, "desperate measures seem less desperate" when a condition is recognized as having only a fatal or hopeless outlook, and "with application and courage, not infrequently can be made safe." To this end, we believe, anesthesiologists can contribute.

Without an attempt at oversimplification, the basic lesion and subsequent pathological physiology of rheumatic heart disease in which there is deformity of the

mitral valve, as already stated, should perhaps be further explained as follows: There is fibrosis of the mitral valve with or without regurgitation. When this fibrosis becomes well developed, a rigid slit in a fibrotic plaque replaces the normal mitral valve. This pathological change produces increasing back pressure on the left auricle and the pulmonary circuit, with resultant hypertrophy of the right side of the heart. The high pressures produced result in accidents to the pulmonary circulation or failure of the right side of the heart or both.

DEFINITION OF COMMISSUROTOMY

When the usually encountered consequences of mitral disease are considered, it is not surprising that as early as 1902, Brunton,[4] an internist, suggested the possibility of a direct surgical attack on the mitral valve. Digital dilatation of the stenotic mitral valve was performed by Souttar in 1925, with success in one case.[5] At our institution digital dilatation, since termed finger fracturing of the mitral orifice, was performed in three cases, with one success. The first patient was operated on on June 12, 1946 [2a]; death within 72 hours was shown at necropsy to have been caused by clotting at the torn commissures.

Systolic Pressure Within the Auricle During Surgery

V. S.	30.2/16.0	22.1/7.5
G. B.	45.5/7.8	39.0/6.5

* Pressures recorded by Lilly manometer.

During the postmortem examination, the possibility of cutting the mitral valve commissure into flexible tissues just beyond the fibrotic structures was first considered. This procedure, defined as "commissurotomy" as a result of a suggestion by Durant, is a procedure designed to reestablish a considerable degree of normal valvular function, as compared with procedures substituting regurgitation for stenosis. The method has been adequately described, and the description will not be repeated here. When correctly performed, it relieves the tremendous back pressures resulting from the stenosis, with excellent return of valvular function. As an illustration: By means of cardiac catheterization at the time of the surgical procedure, immediately before cutting of the valve, in one patient the preoperative systolic pressure in millimeters of mercury in the left auricle was reduced by commissurotomy from 45.1 to 14.5, while the diastolic pressure in the left auricle was reduced from 30.3 to 2.6. Fifty patients have been subjected to commissurotomy; eight did not recover.[5a] One patient recovered from the operation and was progressing satisfactorily six months later, when she died as a result of an upper respiratory tract infection and bronchopneumonia.

SELECTION OF CASES

The cases in which a surgical procedure is to be performed are carefully studied and selected. Fluoroscopy is done, electrocardiographic tracings and phonographic recordings are made and circulation time and venous pressures are determined. Catheterization of the right heart and pulmonary artery is important. Patients are studied by a cardiologist, who takes into consideration preoperative pressure readings from the pulmonary arteries and right ventricle and auricle in contemplating results. Ballistocardiograms and studies of cardiac output also are of value.

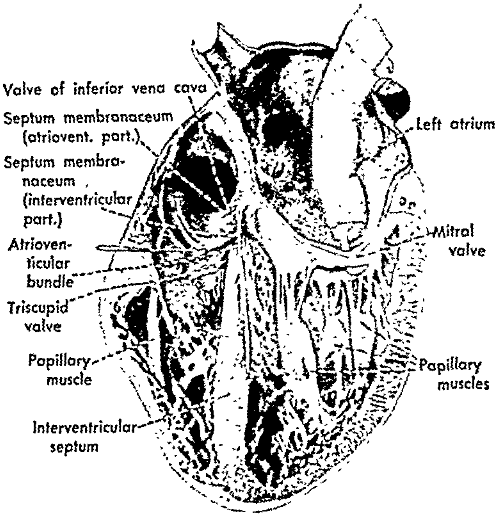

Fig. 1.—Commissurotomy knife on finger, showing method of cutting the mitral valve.

We believe that the most favorable group consists of those patients with mitral disease who have excessive fatigability and increasing exertional dyspnea—but no active rheumatic disease—and whose sinus rhythm is normal, in whom the lesion is predominantly stenotic and in whom there is evidence of significantly increased pulmonary hypertension.

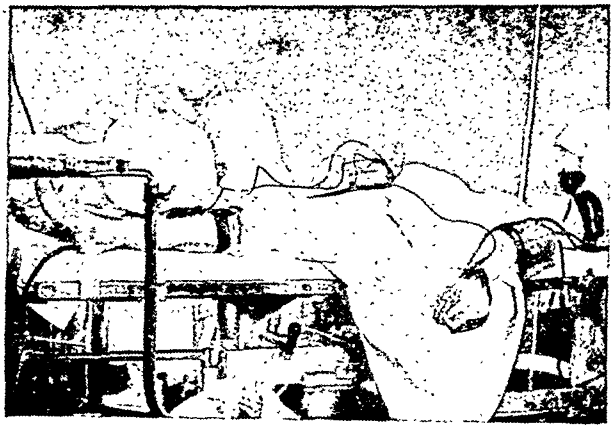

Fig. 2.—Equipment for electrocardiographic tracings in place, patient ready for induction of anesthesia.

A less favorable group, but one for whom surgical intervention is not necessarily contraindicated, consists of those patients who have the symptoms cited above plus recurrent bouts of hemoptysis arterial embolic phenomena and auricular fibrillation without failure. At the present time, the presence of auricular fibrillation is not considered a contraindication to the procedure.

[5] Souttar, H. S.: The Surgical Treatment of Mitral Stenosis, Brit. M. J. 2:603-606 (Oct. 3) 1925.

[5a] Since this presentation was made, 116 commissurotomies were performed prior to Jan. 1, 1951, with 14 fatalities. From Jan. 1, 1951, to April 1, 1951, 16 were performed with 6 fatalities.

Surgical intervention, however, is not instituted in the presence of active rheumatic infections, superimposed subacute bacterial endocarditis, cardiac failure uncontrollable by medical means, or marked associated mitral regurgitation or other valvular (aortic) deformities.[2a]

In addition, before a surgical procedure is advised, any previous infarction should be proved to be healed. Patients who are in failure or on the verge of failure are given digitalis both before and after operation. Early in our series of operations it had been customary to employ quinidine sulfate to counteract the irritability of the heart. In one case it appeared to us that there was a synergistic effect between the quinidine sulfate and our method of anesthesiologic care, which so reduced the irritability of the heart that when cardiac arrest occurred cardiac contraction could not be reestablished. Since that one experience, although our department of pharmacology has not been able to duplicate our suspected summation of the effects of quinidine sulfate and procaine, neither quinidine nor any other agent has been employed for that purpose, with the exception of procaine.

PREANESTHETIC PREPARATION

The preanesthetic preparation, medication and anesthesiologic care are directed toward (1) decreasing the irritability of the heart, (2) lessening any factors such as nausea, vomiting, coughing or straining that may be present just before, during or in the immediate postoperative period, because of their effect on increasing pulmonary hypertension with edema, and (3) increasing the already restricted vital capacity of the patient.

PRELIMINARY MEDICATION

Preliminary medication is aimed toward having the patient rested and the metabolic rate as nearly normal as possible without depression. Pentobarbital (nembutal®), 0.10 to 0.20 Gm. (1½ to 3 grains), or secobarbital (seconal®) sodium in the same dosage is prescribed the night before operation. From an hour to an hour and a half before anesthesia, 0.10 Gm. of pentobarbital (1½ grains) is given by mouth, and meperidine (demerol®) hydrochloride, 75 to 150 mg., with atropine sulfate, 0.60 mg., (1/100 grain) are given intramuscularly. Shortly after administration of these drugs a vein in the lower extremities, usually the anterior tibial vein, is cannulated under infiltration anesthesia.

MANAGEMENT OF THE PATIENT IN OPERATING ROOM

After the patient is brought to the operating room, absolute quiet is essential. The equipment for making electrocardiographic tracings and determinations of blood pressure is applied after the patient has been placed in a supine position on the operating room table.

Thirty minutes before induction of anesthesia, a solution of 0.2 per cent procaine in 5 per cent dextrose and distilled water is administered intravenously in the operating room. From 350 to 750 mg. of procaine is given before intubation is carried out. As a result of administration of this combination of drugs, our patients are calm and have received sufficient procaine to obviate the majority of extrinsically caused cardiac irregularities. Usually some slowing of the heart rate can be demonstrated. In addition, procaine, so administered and continued, produces a degree of analgesia beneficial to the patient.

At the time of the preanesthetic examination, and again before anesthesia is induced, an attempt is made to explain the steps of the procedure of which the patient may be aware during operation. This includes the curare-like action of decamethonium bromide (syncurine®). Decamethonium bromide in doses varying from 1 to 4 mg. is administered intravenously until the patient experiences difficulty in opening and closing his eyelids. Thiopental (pentothal®) sodium is then given intravenously in dosages sufficient to produce hypnosis (250 mg. or more). By this time, approximately 350 mg. or more of procaine has been given. A Magill endotracheal catheter is passed under direct vision by the oral route. With this method we have rarely seen a patient "buck" or fight the introduction of an endotracheal tube. A mixture of 50 per cent nitrous oxide and 50 per cent oxygen is administered from the time the patient loses consciousness. During all steps apnea is avoided with its ensuing, although temporary, hypoxia. Whenever indicated, respiratory function is augmented to assure adequate pulmonary ventilation with both adequate oxygen delivery and carbon dioxide elimination. Administration of nitrous oxide and oxygen in this concentration is continued until the left auricular appendage is opened by the surgeon, when 100 per cent oxygen is administered. Procaine is continued at the same concentration of 0.2 per cent, with a basic flow of 1 Gm. per hour. Thiopental sodium is added as required for basal hypnosis. We believe that analgesia and anesthesia result from the combination of procaine, nitrous oxide and thiopental anesthetics.

Fig. 3.—Anesthetized patient ready for draping.

Continuous or semicontinuous electrocardiograms are taken during the surgical procedure. All surgical activities are interrupted if ventricular tachycardias appear, as determined either by electrocardiographic means or directed vision, because we believe that if a ventricular tachycardia is allowed to persist for a longer period than from eight to 10 or slightly more contractions, ventricular fibrillation may occur. With cessation of manipulation, normal cardiac rhythm is usually restored. It is particularly dangerous to overload the cardiovascular system with fluids that easily produce pulmonary edema, especially in these cases. Solutions of sodium chloride are not employed because of their well known effect in this respect, as well as the possibility of oliguria occurring after operations. Whole blood is administered as indicated. From the viewpoint of anesthesiology, we whole-heartedly advocate the physiological rectification of hypotension brought about by shock, in contradistinction to pharmacologic treatment of the condition by means of drugs. Usually but little blood is lost, because of the present perfection of surgical technic.

At the completion of intracardiac manipulation, the rate of flow of procaine is decreased. Usually thiopental sodium need not be added after the approximation of the chest wall has been started. We attempt to have these patients awake, moving and responsive at the completion of surgery.

We have been alarmed by symptoms produced by a change of position, such as elevation of a shoulder, during the operative procedure. In such cases the heart could conceivably be further dislocated once the procedure is initiated. For this reason, we attempt to avoid any change of position once the pericardium has been opened.

POSTANESTHETIC MANAGEMENT

Immediately after operation, a thorough tracheobronchial toilet is performed, and if superficial reflexes have returned, as is the usual experience, extubation is carried out. If the blood pressure and pulse rate are stable, the venous cannula is removed in order to avoid a temptation to administer excessive intravenous fluids. If pulmonary edema is present, oxygen under positive pressure is administered until there is no further evidence of this complication. Administration of oxygen is continued by means of nasal catheter for varying periods. A limited fluid intake is prescribed. Sedative drugs may be given, but depressants should be avoided. The patient is usually ambulatory in from three to five days.

SUMMARY

A preliminary report on the anesthesiologic management of 50 cases of mitral commissurotomy is presented.

ABSTRACT OF DISCUSSION

Dr. Lloyd H. Mousel, Seattle: Dr. Ruth and his associates have had an exceptional opportunity in the development of anesthetic methods for this new intracardiac surgical procedure. Dr. William Derrick at the Peter Bent Brigham Hospital has had the opportunity of anesthetizing a substantial group of patients for mitral valvuloplasty. All patients in his group were considered exceedingly poor risks, many of them having been entirely bedfast for periods of six months to four years prior to operation, and many of them having had acute bouts of cardiac failure and pulmonary edema. Derrick states that the development of preoperative tachycardia has given them great concern. In several patients tachycardia and pulmonary edema, due probably to increased pulmonary hypertension, developed on the day before operation had been scheduled. He attributed this condition to the apprehension in the patient. Following their early experience of having to postpone surgical intervention because of right heart failure, he has "stolen" the patient by the intravenous administration of thiopental (pentothal®) sodium, given in the patient's room. Following the thiopental injection, ether has been used as the main anesthetic agent. One patient was anesthetized successfully with ethylene and oxygen. Derrick has not used the intravenous administration of procaine routinely, withholding it for use in 20 to 40 mg. doses in those cases where cardiac arrhythmias are noted on the continuous electrocardiographic tracings. In all of his patients the pericardial sac has been flooded with a 1 per cent solution of procaine as soon as it has been opened. No mention has been made, in either Derrick's or Ruth's report, of myocardial infiltration. This procedure was first used by Horace Smithy, and later by Blades, Blalock, Bailey and others. Apparently the myocardium can be infiltrated safely prior to the placement of a purse-string suture around the area to be incised. Local anesthesia in this area tends to prevent arrhythmias from extrinsic stimulation. A 1 or 2 per cent procaine solution is not of adequate strength to reduce myocardial irritability. I would recommend that a 5 per cent solution be used in the pericardium, and that the heart be allowed to swim in this solution for several minutes before the incision is made in the auricular appendage. In patients with mitral stenosis pulmonary hypertension develops. If intrapulmonic pressures are increased above the patient's compensated level, right heart failure may be expected. This possibility should be borne in mind in all anesthetic management. Working with dogs, Pierpont, Blades and I found that controlled and supported respiration increased pressures within the pulmonary arteries and right ventricle greatly above normal levels. It seems possible that controlled respiration or too vigorous supported respiration in patients with mitral stenosis might increase pulmonary hypertension to such an extent that right heart failure with pulmonary edema could develop in a short period of time. The same condition might result from the application of positive pressure oxygen or air in an attempt to treat pulmonary edema in patients who have pulmonary hypertension. We know too little regarding the hemodynamics of pulmonary and cardiac circulation during our positive pressure and controlled respiratory manipulations. A great amount of research in the physiology of circulation needs to be done soon, in order that our anesthesia improvements can keep pace with the newer developments in intracardiac surgery.

Dr. W. O. McQuiston, Peoria, Ill.: The results reported by Dr. Ruth and his associates are spectacular. The patients in this series could by no stretch of the imagination be considered even fair anesthetic risks. Commissurotomy in the adult is a much more difficult and dangerous procedure than commissurotomy or valvulotomy in the child, just as division of a patent ductus or excision of a coarctation of the aorta in the adult is a much more formidable procedure than the same operation in the child. Since I have had no experience with intracardiac surgery in the adult, it would be presumptuous, and possibly dangerous, to suggest that the relatively simple anesthetic technique that we have used successfully for intracardiac surgery in children might also be adequate for the adult. However, in children, at least, other agents and techniques may be used. We attempt to reduce the metabolism without respiratory depression, by administering relatively large doses of morphine and scopolamine or atropine preoperatively. Morphine has always been our favorite sedative drug for cardiac patients, and we wonder if Dr. Ruth uses meperidine (demerol®) hydrochloride for intracardiac surgery because of its spasmolytic action, and if he prefers it to morphine for all types of cardiac patients. We have used cyclopropane for all our intracardiac surgery as well as for exploration inside the pericardium. After the pericardial sac is opened, 1 per cent solution of procaine is poured into the sac, bathing the heart with procaine for at least five minutes before the heart is opened or handled. Arryhthmia has not been noted. By means of this technique four patients—23 days, 2 months, 11 months, and 10 years of age—have undergone pulmonary vavulotomy with no mortality, and several children have undergone extensive intrapericardial explorations. Adequate pulmonary ventilation with an atmosphere rich in oxygen has been stressed by Dr. Ruth. After experience with over 500 patients undergoing cardiac surgery, it is my clinical impression that oxygenation is the most important factor in preventing cardiac disturbances. We feel that unassisted or occasionally assisted respiration when the chest is opened may result in inadequate pulmonary ventilation, and we therefore use controlled respiration on all patients. The danger of overloading the cardiovascular system with fluids cannot be overemphasized. With too much fluids pulmonary edema and/or cardiac decompensation may occur. We administer a 50 per cent dextrose solution intravenously if edema occurs, and digitalize the patient with one of the drugs for intravenous administration if cardiac decompensation occurs.

Dr. Henry S. Ruth, Philadelphia: Emphasis should be placed on the fact that we not only have used the method presented to you, which is the method of anesthesia management we employ at the present time, but have also employed ethyl ether, cyclopropane and other drugs. In our hands, at least, these agents did not provide as satisfactory results. Instillations of the higher percentages of procaine in the pericardium after it has been opened and after the injection of the auricular appendage, were not called to your attention because they are performed by the surgeon, and limitations of time prevented us from discussing any portion of the surgical management in great detail. I do not believe that Dr. Mousel's criticism of oxygen administered under pressure applies to our use of it in the manner reported. If you will recall, oxygen under pressure for the treatment of pulmonary edema was listed under postanesthesiological care. It is to be remembered, too, that the pressure in the pulmonary circuit is relieved by commissurotomy. Therefore, no greater precautions in the utilization of oxygen under pressure appear to be indicated here than elsewhere. Lastly, to answer a question by Dr. McQuiston: We are using meperidine (demerol®) hydrochloride for spasmolytic effect, and, also, because we believe less nausea and vomiting follow its use. Any bouts of postoperative nausea and vomiting are, of course, not well tolerated in these patients.

HYPERTHYROIDISM WITHOUT APPARENT HYPERMETABOLISM

Sidney C. Werner, M.D.
and
Howard Hamilton, M.D., New York

A recent study in this clinic of the newer laboratory technics for appraising thyroid function [1] has revealed several points of interest. First, the evaluation of a single function of the gland, such as the ability to take up radioiodine [2] or to maintain the level of precipitable iodine in the serum,[3] does not always reflect the over-all activity of the gland. Second, the appraisal of several functions of the thyroid has not overcome this difficulty. The determination of the levels of both radioiodine tracer uptake and serum precipitable iodine chemically, or of tracer uptake and basal metabolic rate, provides, with about 95 per cent accuracy, a reflection of gland activity, but it is still not pathognomonic of either hyperthyroidism or hypothyroidism. Third, despite this limitation, the use of the newer technics has permitted the characterization of a hitherto poorly recognized group of patients who have hyperthyroidism but no apparent concurrent elevation of basal metabolic rate.

An analysis of the data from 15 such patients seen at the Presbyterian Hospital in the past year is the subject of the present report. There are several of the 15 patients in whom the clinical picture was induced during radioiodine therapy for hyperthyroidism.[4] As a consequence, we had considerable difficulty in establishing whether control over toxicity was in part or was entirely achieved.

The concept that hyperthyroidism may occur without ostensible hypermetabolism has received sporadic attention in the literature.[5] However, these papers have not won acceptance of the entity by all clinics. The well known difficulties in clinical differentiation between hyperthyroidism and anxiety or other psychoneurotic states [5e] has made for skepticism toward a diagnosis, which has to be made in the face of lack of support from the laboratory. Swenson and Curtis [6] most recently have been interested in the problem. They studied diffuse and nodular goiter and noted a group of patients with normal basal metabolic rates, but with elevation of the serum iodine level. They postulated that these patients might have toxicity from goiter. Soisalo, however, in a similar series could not entirely concur with this interpretation on the basis of a more detailed iodine tolerance test.[7] Moreover, the relatively high incidence of elevated values of serum iodine in euthyroid subjects proved not to have hyperthyroidism [8] makes difficult the acceptance of this test as a final diagnostic criterion for the individual patient.

In order to avoid question, a definite response to therapy has been required in the present study, in addition to laboratory evidence from the radioiodine tracer, serum precipitable iodine and basal metabolic rate determinations, before a final diagnosis of hyperthyroidism without apparent hypermetabolism has been accepted.

METHODS

All patients were seen either in the hospital or in the thyroid clinic by one of us (S. C. W.). Adequate follow-up has been possible after initiation of therapy in all but one patient. This patient's data have been included in the tables since there is little doubt as to the correctness of the diagnosis.

From the Department of Medicine, College of Physicians and Surgeons, Columbia University, and the Presbyterian Hospital.

Read before the Section on Internal Medicine at the Ninety-Ninth Annual Session of the American Medical Association, San Francisco, June 28, 1950.

This investigation was supported (in part) by a grant from the Division of Grants and Fellowships, National Institutes of Health, United States Public Health Service.

Customary clinical and laboratory procedures have been employed to establish a diagnosis and evaluate the results of treatment. Basal metabolic rate determinations were performed in the routine basal metabolism laboratory with the use of a Benedict-Roth apparatus. Two or three readings of five minutes each were made after the usual 30 minutes of bed rest. Spirograms were reviewed and considered satisfactory in all patients listed except one with a habit spasm, champing of the jaws.

Diarrhea	2	7	0	1
Eyes	0	15	0	2

The uptake of radioiodine was measured directly over the gland 24 hours after the ingestion of 40 microcuries of I^{131}, as previously described.[9] The chemical determination of precipitable iodine in the serum was done by the method of Barker.[3c] The determination of serum cholesterol was done with the patient in the fasting state by the method of Bloor.[10] The inherent inaccuracy of the method is recognized, but experience indicates that rising levels usually represent clinical improvement.

* Pulse rate in group 1 ranged from 86 to 120 per minute. Pulse rate in group 2 was 100.

The result of a trial period of administration of a sedative or sodium iodide was observed in several instances for confirmation of the clinical impression. Definitive therapy was undertaken with radioiodine in six instances, propylthiouracil in five and surgical intervention in one. Sodium iodide alone was given in two. No treatment was possible in the one patient lost to follow-up. Of the two patients thought not to have hyperthyroidism, one received roentgen therapy, and the other antithyroid drug in the same dosage as the other patients. There was no response in either instance.

RESULTS

Clinical Observations.—The history and physical examination of each of the 15 patients considered to have hyperthyroidism (group 1) has been analyzed (tables 1, 2 and 3). There are 13 women and two men, whose ages range from 21 to 61 years. Two additional patients thought not to have toxic goiter because of lack of response to therapy (group 2) are included in the tables to emphasize the inherent error in reliance on laboratory findings alone. Their ages were 34 and 63 years, respectively.

A clinical suspicion of hyperthyroidism was present in almost every instance prior to investigation. Nevertheless, the symptom picture was equally consistent with the manifestations of a neurosis, such as anxiety state or neurocirculatory asthenia. As a result, there was generally no uniformity of opinion as to the diagnosis among the several experienced clinicians first seeing a given patient before the reports from the laboratory were received. The most consistent symptoms elicited in the history (table 2) were nervousness in 11 of the 15 patients, weight loss with good appetite in 10, palpitations and fatigability in eight each.

TABLE 4.—*Response of Body Weight to Treatment*

	Weight Gain	
Group	Average, Lbs.	Range, Lbs.
1	7	3-14
2	+1, −1	+1, −1

The one consistent finding on physical examination (table 3) was tachycardia, noted in all 15 patients, with pulse rates between 86 and 120 per minute. Warm moist palms were noted in eight. A readily palpable gland was observed in five patients. The gland was barely palpable in five and was impalpable in the other five. Tremor of the extended hands was present in nine patients, fine in character in five of these and coarse in the other four. No tremor was apparent in four, while the observation was not made in one. Weight gain (table 4) and subsidence of symptoms and signs were noted in response to treatment in all the patients diagnosed as having hyperthy-

roidism except in the one patient not adequately followed, of whom proper observation was not possible.

Laboratory Findings.—The levels of tracer uptake and serum precipitable iodine chemically are abnormally high in the patients presented in this report, since this has been a requirement for diagnosis (table 5). The results of the basal metabolic rate determination before definitive treatment range from + 1 per cent to + 16 per cent, with an average of + 11 per cent.

There is only one basal metabolic rate value of + 16 per cent; nine of the remaining fall between + 10 per cent and + 15 per cent and five between ± 0 per cent and + 10 per cent. The selection of + 15 per cent as the upper limit of normal for the basal metabolic rate is based on the fact that in this laboratory, approximately 25 per cent of concurrently tested and proved euthyroid patients have basal values in excess of + 10 per cent and about 15 per cent in excess of + 15 per cent.[1] Thus distinction between thyroid overactivity and anxiety or hypertension on the basis of a basal metabolic rate determination in the + 10 per cent to + 15 per cent range is virtually impossible from this evidence alone.

The highest level of radioiodine tracer uptake for the hyperthyroid group presented herein is 77 per cent uptake at 24 hours. There are nine uptake values greater than 50 per cent at 24 hours, five values between 40 and 49 per cent and one value of 38 per cent. Over-all experience with the method reveals practically no incidence of uptake greater than 50 per cent at 24 hours in euthyroid subjects, although 10 per cent of patients without known thyroid disturbance take up 40-50 per cent of the tracer dose at 24 hours.[1]

Table 5.—*Laboratory Values Before and After Treatment*

	BMR, %		Cholesterol, Mg./100 Cc.		Radioiodine Uptake, % at 24 Hr.		S.P.I., Gamma/100 Cc.	
	Before	After	Before	After	Before	After	Before	After
Group 1								
Average	+ 11	6	176	234	55	..	13.1	7.2
Range	+ 1-+ 16	— 18-+ 8	111-249	181-371	38-77	..	9.3-25.9	5.6-8.9
Group 2								
Range	— 20-± 0	— 18-+ 3	153-199	238	60	30	9.3- 9.8	...

Serum precipitable iodine levels in the hyperthyroid group range between 8.4 and 25.9 gamma per 100 cc. The average for the series before treatment is 13.1 gamma per 100 cc. The upper limit of normal for the method is considered as 8 gamma per 100 cc. It is generally agreed that about 5-10 per cent of serum iodine values may exceed 8 gamma per 100 cc. in apparently euthyroid subjects, often by a considerable margin.

The values for fasting serum cholesterol are listed in table 5. There is no definite trend indicated by the results. The normal range by the method used is approximately 150-250 mg. per 100 cc.

Treatment of hyperthyroidism in these patients is followed by a definite fall in basal metabolic rate, a return of the serum precipitable iodine level toward normal and a slight rise in serum cholesterol. The correlation between tracer uptake and hormone release may be disrupted by therapy [2c] so that this test was not followed after treatment.

COMMENT

The concept that hyperthyroidism may exist without apparent elevation of basal metabolic rate appears to have been confirmed. This statement applies to the basal rate determination as done routinely in the laboratory and has not been subjected to verification by special technics. These persons mainly have been classified in the past as neurotic or hypertensive on the basis of the relatively normal result of the basal metabolic rate determination. The introduction of the radioiodine tracer test has made it relatively simple to screen out for further study [11] those patients with elevated uptake. Confirmation of possible hyperthyroidism should then be sought by the serum precipitable iodine and basal metabolic rate determinations. However, even with support from the laboratory data, it must be emphasized again that further documentation of the possibility of toxicity from goiter must be found in a favorable result from therapy before the diagnosis can be said to be complete.

There is real danger that innumerable patients with neuroses, anxiety state, hypertensive disease or some extraneous disorder may be treated for hyperthyroidism if reliance is not placed on all these criteria. In case of doubt as to the ultimate result to be expected from treatment, information frequently may be gained by the administration of sodium iodide for a two week period.[12] A favorable response to the drug is indicated by weight gain, by amelioration of toxicity and often by some decrease in basal metabolic rate. Serum precipitable iodine values tend to decrease under the influence of sodium iodide. A return of toxicity should follow discontinuance of sodium iodide.

The production of hyperthyroidism without elevation of basal metabolic rate after incompletely successful radioiodine therapy of toxic goiter (table 1) is of interest in terms of the mechanism of action of radioiodine. It appears likely that a quantitative reduction of functional thyroid tissue accounts for the remission induced by this treatment, rather than that a physiopathologic process is interrupted. It is also apparent that the clinician must be alert to the possibility of this type of borderline toxicity when control over toxicity is not quite complete after forms of therapy for hyperthyroidism other than radioiodine. A basal metabolic rate between ± 0 per cent and

+ 15 per cent cannot be relied on too heavily as an indication that complete remission from toxicity has been obtained.

SUMMARY

Hyperthyroidism without apparent hypermetabolism has been observed in 15 patients at the Presbyterian Hospital within the past year. It has been required for the diagnosis that the values for both radioiodine uptake and serum precipitable iodine chemically determined be elevated and that there be a satisfactory response to therapy subsequently. It is stressed that these rigid criteria must be maintained if needless treatment of countless neurotic and hypertensive patients is to be avoided. The clinical picture and laboratory findings in this group are summarized. Two additional patients are reported with laboratory findings consistent with the diagnosis of hyperthyroidism but with lack of response to treatment.

ABSTRACT OF DISCUSSION

Dr. M. Paul Starr, Pasadena, Calif.: It is no surprise to me that this excellent paper by Dr. Werner points out that there are some persons with hyperthyroidism who have a basal metabolism within the normal range. With regard to the rate of uptake of radioactive iodine, which I also have studied, I think that it measures the activity of the thyroid gland in its relation to the metabolism of iodine and does not have much to do with whether or not the patient has hyperthyroidism. From the experiences I have had in being consulted with regard to radioactive iodine, I would like to have the profession realize that it is no more pathognomonic or diagnostic than other laboratory methods; in fact, the uptake, I feel, is rather unreliable as a diagnostic procedure. The basal metabolic rate test is unreliable because it is nonspecific, since it measures the total oxygen found in the body, which is influenced by many things that are not directly dependent on the thyroid hormone. On the other hand, it seems to me that the protein-bound iodine, which measures the level of the thyroid hormone in the blood, is the most reliable diagnostic method. One trouble in this whole discussion is that none of us is clear about what hyperthyroidism is, and since we cannot define what we mean by the disease, it is a little hard to decide what is the best diagnostic test for the disease. In one sense, we are studying the thyroid too much; whereas we should think of the disease as a failure of homeostasis. Dr. Means suggested this several years ago. The condition we are thinking of as Graves' disease or hyperthyroidism is a failure in some response to stress. We all have stresses. The patient with hyperthyroidism, however, cannot get back to normal. The patient's history and complaints are a poor guide to whether or not he has the disease. Dr. Mayo Soley laid down a dictum sometime ago which I think was to the point, i. e., that many patients with hyperthyroidism cannot tell you whether or not they have hyperthyroidism until they have been relieved of the hyperthyroidism; in other words, they have to return to a euthyroid state and homeostasis must be restored before they can think properly about their previous condition and then realize that they were sick. In our hands, the use of the chemical measurement of the protein-bound blood iodine is the most reliable method of diagnosis of hyperthyroidism. I would like to emphasize the chemical determination of the disease in this case just as one uses the chemical determination in diabetes. The experience in the Diabetic Association throughout the country has been that there are many people who have diabetes without knowing that they have it, but that it is demonstrated by the chemical determination of excess sugar. I believe that the same thing is true of hyperthyroidism with relation to excess thyroid hormone iodine.

Dr. Edward D. Robbins, Chicago: Ever since the introduction of clinical calorimetry, there has been a regrettable tendency to identify the basal metabolic rate more or less exactly with the function of the thyroid. But it is known that this gland contributes at most 40 per cent to the total basal metabolic rate, that many morbid processes other than thyroid disease affect the basal metabolic rate and that the basal metabolic rate may deviate considerably from so-called "normal" without thyroid dysfunction being present. Hyperthyroidism, hypermetabolism, hypometabolism and perhaps even hypothyroidism may exist as independent variables. It is common knowledge that a large number of nonmetabolic diseases, e. g., pheochromocytoma and leukemia, may produce states of hypermetabolism without hyperthyroidism. Drs. Werner and Hamilton have described cases of hyperthyroidism without hypermetabolism. There is excellent evidence that most patients with low basal metabolic rates but without myxedema have hypometabolism but not hypothyroidism. Further, many patients with undernutrition and anorexia nervosa have low basal metabolic rates without hypofunction of the thyroid. There may be one rather obvious explanation for the six cases in this report that had no previous treatment. The normal distribution curve for the basal metabolic determinations on patients without metabolic disease is a gaussian one, and while 95 per cent of patients fall between —18 per cent and + 22 per cent, 2½ per cent of these patients have basal metabolic rates below —18 per cent. When a euthyroid person whose basal metabolic rate is normally —20 per cent develops hyperfunction of the thyroid gland sufficient to raise his basal metabolic rate 30 points, it is then + 10, which is still within the so-called "normal" range. There are some reservations which must be borne in mind when one interprets data from thyroid uptake studies with I^{131}: First, Salter has emphasized that to measure the turnover rate of iodide to hormonal iodine, which is what we are really interested in, one must make simultaneous measurements of isotope and stable element. Second, when one measures the total isotope content by an external counter, one measures the avidity of the gland for iodine, but not the turnover rate of iodide to hormonal iodine. It is possible that cases of high isotope uptake after partial destruction of the gland by radioiodine or subtotal thyroidectomy are caused by hyperplasia of the remnant of the gland and/or by decrease in total body iodine which results from loss of part of the thyroid gland with its stored iodine.

Dr. Earle M. Chapman, Boston: As a member of Dr. Mean's clinic, I want to say that we have seen recent cases of this kind. We recently studied two such cases thoroughly for comparative data. One of these women was treated for what was called rheumatoid arthritis for a period of two years, and we presented her in our clinic, where it was agreed she was not thyrotoxic and yet her uptake of radioiodine was 90 per cent and her protein-bound iodine was up about 12 to 13 micrograms. We have not yet undertaken therapy with her. We had another similar case, and in all, I think we will be able to collect about eight or 10 such cases now in our clinic.

The Quality of Medical Care.—In these stormy and controversial days, much is being said about problems, real or imagined, in the general area of medicine as they relate themselves to society at large. Particularly do we hear about difficulties in the quantity and distribution of medical care, and in the economic mechanism of the provision of adequate medical care. The factors of quantity and economics have tended to obscure far too often the basic fact that the existence of medical care and the ability to buy it are essentially in vain if the care is not of the highest quality. The research laboratories have put into the hands of the practitioners of medicine in all fields, tools which are in a sense double-edged swords. When applied with skill to a medical problem, these tools can be of enormous diagnostic and therapeutic good. When applied carelessly and without complete knowledge, these tools may reap havoc. Therefore, it is incumbent on everyone who concerns himself with medicine increasingly to orient his actions and thinking toward programs designed to deliver to the American people not only adequate amounts of medical care at a price which the people can pay but, perhaps above all else, medical care of the very highest quality.—Franklin D. Murphy, M.D., Postgraduate Education with Reference to Anesthesia, *Anesthesiology*, January 1951.

NASOPHARYNGEAL IRRADIATION

RELATIVE MERITS OF ROENTGEN AND RADIUM THERAPY FOR BENIGN CONDITIONS

L. H. Garland, M.D., H. A. Hill, M.D., M. E. Mottram, M.D.
and
M. A. Sisson, M.D., San Francisco

For many years irradiation has proved to be of considerable benefit in cases of hyperplasia of the lymphoid tissue in the nasopharynx. What are the actual results of treatment in clinical practice? What is the most effective method of irradiation? In an attempt to answer these questions we have reviewed our results in several hundred cases and have summarized the relative physical effectiveness of the two commonly applied methods of irradiation.

ANATOMIC CONSIDERATIONS

In adults the eustachian tubes are about 3.6 cm. in length and the orifices usually 4 cm. apart. The bony portion of the eustachian tube comprises the outer third; it joins the cartilaginous portion at the isthmus, or narrowest part of the tube. The size of the tube increases as it reaches its pharyngeal end. Normally the walls in its mesial half are apposed; its ostium is vertical and slitlike except when forced open by muscular action or positive pressure. The nasopharyngeal orifices of the tubes are surrounded above and behind by the torus tubarius, a prominent bulge composed of cartilage covered by mucosa. Above and behind the torus, is the fossa of Rosenmüller, which is lined with lymph follicles and lymphoid tissue. On the roof and upper posterior wall of the nasopharynx lies the adenoid. Although there is one central area of attachment, it may be very extensive and extend into the fossa of Rosenmüller and even over the torus tubarius. There is no well defined tissue or capsule separating the adenoid from the superior constrictor muscle.

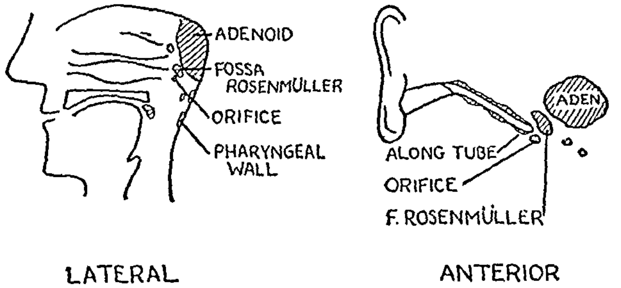

Fig. 1.—Diagrams showing location of pathological changes in benign nasopharyngeal lymphoid hyperplasia. Note the location of shaded areas of hyperplastic lymphoid tissue, especially those along each eustachian tube; the latter deposits develop with repeated or chronic infection.

Scattered superficial bands of lymphoid tissue lie on the posterior and lateral walls of the pharynx and nasopharynx. Both the lateral bands and the scattered nodules are more developed in the upper part of the nasopharynx and less developed inferiorly. This tissue is normally about 2 mm. thick. Farrior,[1] Wolff, Teutleben and Zollner have shown that lymphoid tissue is absent in and about normal tubes. In the presence of acute and chronic infection lymphoid tissue may occure anywhere along the tube and even in the middle ear. The lymphoid tissue is most prominent at the pharyngeal end of each tube, where it is sometimes called the tubal, or Gerlach's, tonsil. The mucous membrane lining of the tympanic cavities and eustachian tubes is continuous with that of the nasopharynx. The pharyngeal ostium acts as a flutter valve, allowing escape of air under pressure from the middle ear but preventing passage of air into the middle ear.

PATHOLOGIC CONSIDERATIONS

The lymphoid tissue comprising Waldeyer's ring is normally "thick" or "hypertrophic" in childhood. About the time of puberty it begins to atrophy, except in cases of infection, when it persists with or without scar tissue formation. With repeated infections, adhesions may form from the adenoids to the torus. The close association of this lymphatic tissue to the nose, sinuses and eustachian tubes seems to be a factor in frequent infection.

The normal air exchange between the middle ear and the nasopharynx is extremely slow. The normal tube does not open with each act of swallowing and may remain closed for long periods of time each day. With edema or hyperplasia of the lymphoid tissue in the eustachian tubes or around their orifices there is blockage, which, if prolonged, leads to changes in the middle ear. Deafness may result by mechanical block or compression of the pharyngeal end of the tube (fig. 1).

In chronic or repeated infections there are hypertrophy of the lymphoid tissue and inflammatory changes that may apparently act as a focus of infection for subsequent development of sinusitis or otitis. Patients may show a granular pharyngitis or mucus hypersecretion. Aviators with lymphoid hyperplasia may get on well until a cold develops with consequent edema of the lymphoid tissue and excess mucus formation; this blocks the eustachian tube, leading to aero-otitis.

There are various stages of aero-otitis, and if the air pressure is increasing, the pressure in the middle ear and nasopharynx must be equalized and the tube opened by means of its muscles, or a definite sequence of events follows. With a difference of 3 to 5 mm. pressure of mercury (at sea level) "fulness" develops in the ears; at 15 to 30 mm. there are discomfort and diminished hearing; above 30 mm. there may be pain, tinnitus, bleeding, vertigo and nausea; at 80 to 90 mm., great pain and exacerbation of all the other findings. When the air pressure in the tube is greatly decreased the veins in its wall will expand and may rupture, with blood and serum filling the middle ear.[2]

Once fluid has formed, its complete replacement by air takes about two weeks even when normal tubal function is maintained. Prolonged tubal obstruction, with or with-

---

[2] Shilling, C. W., and others: Prevention and Treatment of Aerotitis Media, U. S. Nav. M. Bull. 46:1529 (Oct.) 1946.

out exudative catarrh, may produce temporary or irreversible changes in the conduction mechanism. As Crowe[3] and others have pointed out, it is not alone the presence of the lymphoid tissue in the nasopharynx but also its localization at or near the tubal orifices that is important in deafness.

After infection, the torus tubarius shows marked inflammatory changes, particularly around the anterior lip where the mucosa is not bound firmly to the underlying structures. The inflammation may obliterate the orifice completely. Adenoid tissue may reach obstructive proportions. The posterior tips of the inferior turbinates are frequently edematous and show polypoid changes, and although they do not influence the tubes per se, they indicate associated inflammatory conditions. Since there is no clinical means of determining the presence or absence of lymphoid infiltration of the tubal wall beyond the torus, one may reasonably infer its presence when there is generalized lymphoid infiltration of the pharyngeal walls, torus and fossae. Farrior has illustrated the detailed histopathological changes of chronic infection.[1]

SYMPTOMATOLOGY

This brief review of pathological changes presages the wide variety of clinical findings one may encounter in these patients. There may be diffuse inflammation or thickening of the mucous membrane, with excess mucous discharge and postnasal drip. The patients have frequent colds, sore throats, sinusitis and catarrhal otitis; the crypts in the lymphoid tissue are said to be favorable locations for the common cold virus and the bacteria of upper respiratory tract infections. There are stuffiness and fulness in the ears and nose. Buzzing and roaring in the ears are common. There may be intermittent deafness, often improved in the summer months. Progressive deafness, beginning with the highest tones (above 8,000 double vibrations) may develop in patients with chronic eustachian tube block. During World War II aero-otitis (or barotrauma) was of considerable import among Air Force and submarine personnel.[4] Aero-otitis is characterized by middle ear lesions caused by failure to equalize pressure between the middle ear and the surrounding atmosphere. Effects of altitude on the middle ear have long been recognized but recently have been of greater concern because of increased commercial and military aviation. Patients suffering from this condition have otalgia, fulness in the ears, tinnitus and recurrent discharge. The pain in some cases is reported to be so great that there are associated vertigo, nausea and vomiting. The drum may be hemorrhagic and retracted and in severe cases may rupture. With a less severe process, there is reddening along the handle of the malleus and the periphery of the drum, as in beginning otitis. With relatively negative pressure due to oxygen absorption, a transudative fluid appears in the middle ear (serous catarrh) or there is gross bleeding.

TREATMENT

The treatment of choice in hyperplasia of the lymphoid tissue is radiation therapy, since this hyperplastic tissue is not amenable to surgery. This therapy can be applied either by external or intraoral use of roentgen rays or by local nasopharyngeal application of radium. Jarvis, in 1923, first reported on the use of nasopharyngeal roentgen therapy for patients with congested ears. Crowe has been using radium or radon applicators for lymphoid hyperplasia since 1924, and during the recent war radium was used extensively in the medical departments of the Air Force and Navy.

Radium Therapy.—The radium applications are carried out after local anesthesia. The holder is inserted along the floor of the nose to the region of the eustachian tube orifice, so that the radium centers on the orifice and does not enter it. There are a number of different types of holders[5] for the radium, and the one now in common use is made of monel metal, with a wall thickness of 0.3 mm. monel. The active length is 15 mm. and the outside diameter 2.3 mm. Each holder contains 50 mg. of radium. The holders are usually left in place 12 minutes, giving 600 mg. minutes of radiation to each side. This container gives beta as well as gamma rays (fig. 2).

Measurement of the precise amount of radiation emanating from the radium applicator is difficult, and different sets of figures are obtained from the literature. Fowler[6] and Quimby give the roentgens obtained with 50 mg. of radium, using various filters and times (table 1). At the surface of the monel metal applicator the beta rays predominate, while after passing through 1 cm. of tissue the radiation is virtually all gamma. Ionization measurements close to the applicator record the summation of beta and gamma ray "roentgens"; at a distance of about 1 cm. they record the gamma ray roentgens, the beta having been absorbed.

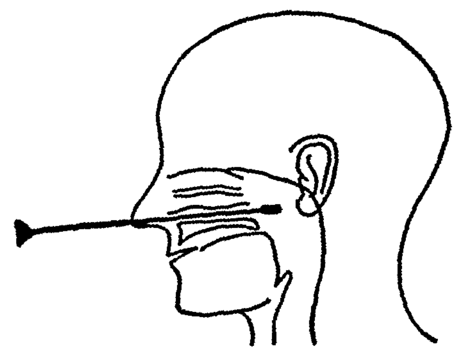

Fig. 2.—Diagram showing usual method of radium treatment. Two standard containers, each with 50 mg. of radium in monel shells 0.3 mm. thick and 15 mm. in length, are inserted following application of local anesthesia. An attempt is made to slide the applicators into place so that the centers of each applicator overlie a eustachian tube orifice. Treatment time is usually 12 minutes. Three treatments are given at two week intervals.

Fowler also gives the estimated tissue dose in roentgens at various depths in tissue from the surface of a standard monel metal applicator, as determined by Quimby (table 2).

Carl Braestrup[7] constructed a series of cylindrical ionization chambers of polystyrene with the inner walls coated with aquadag to make them conducting. By the use of various chambers the air spacing was varied from a few millimeters down to 0.25 mm. Measurements were also made after the rays had passed through tissue-equivalent absorbers. The results obtained by two different measuring systems varied within a few per cent (table 3).

Quimby's and Braestrup's figures, obtained independently, are in close agreement and, in view of their careful work, are believed to be the most accurate available.

In the nasopharynx the space between the tube orifices is 4 cm. and the eustachian tubes are approximately 3.6 cm. in length. Table 4 shows the radium dosage in roentgens at various points in the nasopharynx and tubes.

It has been shown by the above tables that there is a tremendous "fall off" in the roentgens delivered at short distances from the containers. Extremely large doses are given to the eustachian orifices with proportionately little radiation reaching all the other lymphoid tissue in the nasopharynx, the tubes and the middle ear. No other nonmalignant condition is given such heavy radiation. Further, as Fowler observes, "The exact dose in each case varies, since the apparatus lies at different distances from the tissue in different persons." Radium, as generally employed, is therefore potentially useful in control of localized lymphoid hyperplasia but not for the usual patient having aero-otitis with deafness, who has generalized lymphoid hyperplasia.

Table 1.—*Depth Doses in Roentgens Around 50 Mg. Radium Tubes with Various Filters (Quimby)*

		Distance from Applicator								
		1 Mm.			1 Cm.			2 Cm.		
Filter	Type of Ray	6⅔ Min.	40 Min.	60 Min.	6⅔ Min.	40 Min.	60 Min.	6⅔ Min.	40 Min.	60 Min.
0.5 Mm. Platinum	Gamma	.....	1,500	2,250	..	265	400	..	70	100

0.3 Mm. Monel	75% Beta	1,520	.....	.....	55	...	...	15	..	...

Severe epithelitis may result from the above dosages (Fowler). One of us (L. H. G.) has been informed of three patients with radiation ulcers in the posterior nasopharynx from such use of radium. Robbins and Schultz[8] note that erythema on the skin of the forearm has been seen following as little as about 700 r in a single dose. In a benign condition an erythema dose usually should not be exceeded. In acute infections radium should be employed with extreme caution; if not deferred, the dose should be cut in half.

Hendricks' group in the Air Force[4a] treated 6,881 men with 14,045 applications of radium and noted no burns or ulcerations, using eight and one-half minutes, two or three times. He states, however, "Throughout the entire project the rapid shifting of flying personnel made follow-up studies extremely difficult."

The usual precautions for handling and storing radium must be used. Braestrup calculated the dosage received by the operator and estimated that the treating of three patients a week would result in the tolerance dose to the skin of the hands.

Roentgen Therapy.—We believe that the simplest and safest method of irradiation of lymphoid tissue in the nasopharynx is the use of roentgen rays externally. The only "disadvantage," if it can be called such, is that there must be four to six treatments rather than three and that these usually necessitate attendance at a roentgenologist's office or department.

No anesthesia is required. The treatment can be given easily to children. We have treated most of the patients in the age group 1 to 4 without restraints, after the child finds that the initial treatment is painless. We have not had to discontinue treatment because of noncooperation. The great advantage of roentgen therapy over radium is that the whole lymphoid-bearing area of the nasopharynx is included in the field. Thus the entire tubes are treated as well as the adenoids, the fossa of Rosenmüller and the scattered lymphoid deposits on the nasopharyngeal walls. Further, the dose is relatively homogeneous in comparison with the exceedingly uneven dose around the radium tubes. Centering can be accurate and easily duplicated.

Roentgen ray treatment usually consists of the use of medium or high voltage beams 140 to 200 kvp, with a half-value layer of 0.3 to 1.0 mm. Cu. The field sizes in the literature vary considerably and range from a 5 cm. circle to 10 by 15 cm. fields. The distance also varies but is usually 40 cm. Treatments range from 75 to 150 r each and from three to six in number (fig. 3). We have found 140 kvp with a half-value layer of 9 mm. Al. to be entirely satisfactory, although we often treat patients with 200 kvp and a half-value layer of 1 mm. Cu. The field size should be small enough to avoid dryness of the mouth but adequate to cover all the involved area. We employ a vertical field 6 by 7 cm. in size. Usually six treatments of 100 to 150 r air to each side are given at weekly intervals. The patient is immobilized in lateral position and the fields centered carefully 1 to 2 cm. anterior to the inferior border of the tragus (this is approximately over the temporomandibular joint).

The average adult skull measures 14 cm. in width at the level of the nasopharynx; the eustachian tube orifices are 5 cm. deep. The variations in skin and tissue dosage in roentgens at the orifices and midline are compared in table 5, using beams of various half-value layers and giving 100 air r to each side with a 50 square cm. field.

It is thus seen that half-value layer 1 mm. Cu. is the most efficient of the three beams but that there is little difference between employing half-value layer 9 mm. Al. and half-value layer 1 mm. Cu. With these doses the treatment time is short and the skin dose well below the erythema dose. No late skin changes have been noted during a period of 20 years, and no permanent loss of facial hair. No changes have been seen or reported in the temporomandibular joint.

RESULTS OF TREATMENT AS REPORTED IN THE LITERATURE

Radium Therapy.—Because of the variation in radium and roentgen ray dosage in the literature and variations in presenting complaints, the published results are difficult to compare. These results would have to be analyzed separately for each presenting sign or symptom to be significant. From a multiplicity of reports we present the following results as fairly representative:

Fowler [6] found that, of 66 Air Force personnel, 69 per cent obtained relief of aero-otitis after radium treatments. Shilling [2] reports over 90 per cent improvement in aero-otitis media. He used three to eight radium treatments of eight to 10 minutes each.

Proctor, Polvogt and Crowe [9] report on radium therapy results in 835 patients followed two and one-half to 15 years:

Of 128 treated because of frequent severe colds, 40 per cent showed marked improvement.

Of 110 with postnasal drip due to nasopharyngeal infection, 25 per cent had complete relief, and 75 per cent were improved.

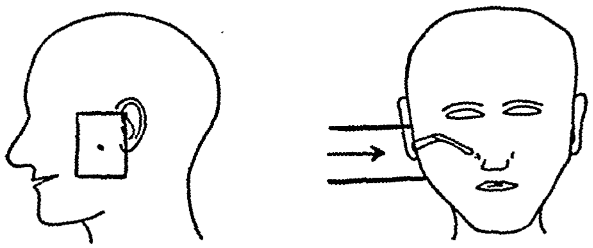

Fig. 3.—Diagram showing authors' method of roentgen treatment. The patient's head is placed in true lateral position. Fields 6 by 7 cm., with the long axis vertical, are centered 1 to 2 cm. anterior to the inferior border of the tragus. Irradiation is given with medium or high voltage beams (half-value layer 9 mm. Al. or 1 mm. Cu.). Doses of 100 to 150 r, measured in air, are given to each side of the nasopharynx, weekly, for six treatments.

Of 282 with impaired hearing attributable to obstructed eustachian tubes, 85 per cent had "great and lasting" improvement.

Of 112 with complaints thought to be attributable to a focus of infection in the nasopharynx, 90 per cent were improved.

Of 87 with partial nasal obstruction due to adenoid tissue, 90 per cent were completely relieved and the other 10 per cent improved.

Of 97 with tinnitus, only three had relief, and, of nine with fulness in the ears, eight were relieved.

A report of the results of radium treatment of the nasopharynx in asthmatic patients is given, among others, by Cohen and Fisher,[10] who consider radium an auxiliary to other types of asthmatic treatment. Proctor and Crowe found improvement in children with bronchial asthma when the asthma was on an infectious basis.

Hendricks [4a] reports on results in the Army Air Force's use of radium for aero-otitis. Because of rapid shifting of flying personnel, follow-up was difficult. Of 575 patients who received two treatments, approximately 65 per cent had objective improvement, and of 778 who received three treatments, approximately 90 per cent had objective improvement. Subjectively, there was a wide variation in the percentage improved, depending on the complaint. Collins, in the same report, found 78 per cent subjective and 94.6 per cent objective improvement 30 days after the third radium treatment in his group of 230 men. The results of the other co-authors in this symposium are similar to those just quoted.

TABLE 2.—*Depth Doses in Roentgens Around 50 Mg. Radium, in Standard Monel Metal Applicator (Fowler & Quimby)*

	Distance from Applicator			
Time, Min.	1 Mm.	2 Mm.	10 Mm.	30 Mm.
8.5	1,940	1,150	42	5
12	2,740	1,620	60	7

TABLE 3.—*Depth Doses in Roentgens Around 50 Mg. Radium in Standard Monel Metal Applicator (Braestrup)*

Depth, Mm.	1 Min.	12 Min. 1 Treatment	36 Min. 3 Treatments
Surface	370	4,450	13,350
0.5	225	2,700	8,100
1	168	2,020	6,050
2	96	1,152	3,460
5	23	276	830
10	5	60	180
20	1.3	14.4	43

Roentgen Therapy.—Rossitto [11] employed roentgen therapy at 200 kvp and half-value layer of 1 mm. copper. The field sizes varied and usually included both the nasopharynx and tonsillar regions. He gave 60 to 125 r to each side four to six times and obtained "90 per cent good results" in children with tonsillitis, sore throat, mouth breathing, nasal obstruction, otitic complaints and, in some cases, asthma. He judged his results in the relief of symptoms by questioning patients and referring physicians.

TABLE 4.—*50 Mg. Radium in Standard Monel Metal Container in Each Posterior Nasopharynx (Using Braestrup's Figures)*

Time, Min.	Dose at Each Tube Orifice	Dose 1 Cm. up Tube	Dose at Midline	Dose 2 Cm. up Tube	Dose 3 Cm. up Tube
12	4,450 r	60 r	28.8 r	14.4 r	7 r
36	13,350 r	180 r	86 r	43 r	21 r

TABLE 5.—*100 Air r Each Side to 50 Square Cm. Field at 40 Cm. Focus-Skin Distance*

KVP	Filter	Half-Value Layer	Skin Dose (Including Exit)	Depth Dose at Each Orifice	Depth Dose at Midline
120	3 mm. Al.	4 Al.	139 r	74 r	66 r
140	0.25 Cu.	9 Al.	147 r	100 r	96 r
200	0.50 Cu.	1 Cu.	148 r	104 r	100 r

Reeves [12] used 100 kv. and 3 mm. Al., filtered, giving 100 r to each side weekly, four to six times. He finds that "Roentgen therapy gives results when all other methods have failed."

Young and Woutat [13] give the results on 116 patients treated for deafness resulting from eustachian tube obstruction by lymphoid tissue. Results were determined by tuning fork tests, ability of the patient to hear the whispered voice and periodic audiograms in all patients old enough to cooperate. Of 63 patients under 15, 72 per cent had significant improvement or return to normal hearing, 17 per cent, partial improvement and 11 per cent, no response. In 53 patients over 15, 49 per cent had noticeable improvement or return to normal hearing, 23 per cent, partial improvement and 28 per cent, no response. Of 36 with chronic otitis, about 61 per cent were healed.

Results of Roentgen Therapy.—We have treated 720 patients for lymphoid hyperplasia in the nasopharynx with the technic as given above. These were, in the main, patients previously untreated, but a few were included who had had unsuccessful radium treatments or in whom radium could not be inserted due to their being uncooperative. All patients were referred by otolaryngologists or general practitioners and suffered from one or more of the usual complaints. The evaluation of results in these patients was made by the patients and/or the referring physicians, who frequently checked progress with audiograms and direct nasopharyngeal observation.

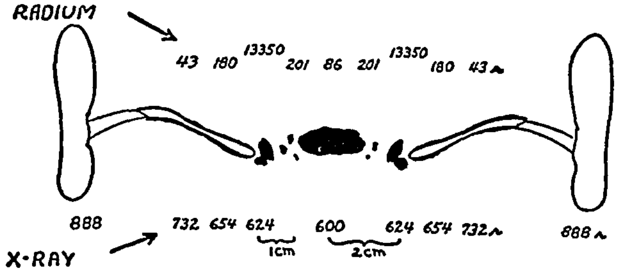

Fig. 4.—Diagram showing the comparative doses of irradiation applied to the pharyngeal and tubal areas during a full course of treatment with radium or roentgen rays. The upper row of figures gives the dose in roentgens received with three applications of radium as specified in the text. The lower row of figures gives the dose in roentgens using roentgen beams as described in the text. Note that much more homogeneous irradiation is obtained with roentgen rays and that the dose at the tubal orifices is excessive with radium.

One of the referring otolaryngologists had been using radium for five years and then had discontinued it in favor of roentgen rays because "Radium gave only localized shrinking of hyperplastic tissue and left the bulk of the lymphoid nodules unchanged." With roentgen rays he noted that about 55 per cent of his adult patients with deafness secondary to hyperplastic lymphoid tissue around the eustachian orifices were cured with a single course. In the remaining 45 per cent "Sufficient lymphoid tissue remained to cause persistent signs or symptoms." Some of these were referred for a second course with good results. His opinion is that almost one half of the adult patients with the complaint of deafness require heavier roentgen dosage than is usually employed to eradicate all the lymph nodules. He has found, over a period of years, that roentgen rays give more satisfactory results than do radium rays, presumably because of their more even distribution of ionization. Another referring otolaryngologist found that approximately 90 per cent of his patients were symptom free after a single course of roentgen therapy. Many of these patients, however, were children and presented a variety of complaints besides deafness.

In our entire series 60 to 90 per cent were relieved of presenting signs or symptoms by the first course of roentgen treatment; the rest had partial or no relief of symptoms. About 5 per cent of the patients returned for additional irradiation, with resultant improvement.

RELATIVE MERITS OF ROENTGEN AND RADIUM THERAPY

Crowe observes, regarding roentgen treatment:

> "Since approximately one-half of the rays delivered at the skin surface are absorbed by neck tissues before they reach the nasopharynx, it is evident that several portals must be used in order to prevent skin irritation. The fact that a large percentage is absorbed necessitates a dosage on the skin surface much larger than is necessary to correct the lesion in the nasopharynx for which the treatment is given. This excessive dosage subjects the centers of ossification for the growing bones of the face and skull to a large amount of radiation which may do harm in a child and is of no value in the treatment of the primary condition in the nasopharynx. Furthermore, it is difficult to maintain young children in a position for accurate cross-firing for the duration of the treatment . . ."

If this paragraph is analyzed, it brings out several interesting points and indicates why roentgen, not radium, therapy is actually advised by many otolaryngologists. In the first place, the use of "several portals" is not necessary; two portals will deliver a satisfactory amount of radiation to all the involved tissues and not merely to the eustachian orifices, as is done with radium. With proper choice of beam, there will be no skin or soft tissue damage (fig. 4).

Comparison of the charts giving the distribution of energy around radium tubes and those for the distribution of roentgen rays shows the tremendous "drop off" in the dosage from the former, so that at 1 cm. there is very little radiation (fig. 4). Since the two eustachian tubes total 7.2 cm. in length and the space between them measures 4 cm., the area of potential lymphoid tissue involvement measures 11.2 cm. in width. This entire zone should be irradiated.

Most of the articles on the use of radium caution against roentgen rays because of "damage to the normal tissues traversed in using external beams." Actually, we have been able to find no reports of damage from roentgen therapy in the doses specified, after an extensive search for such in the literature. We are firmly convinced that in the use of the method we describe there is no danger either to the skin, the underlying soft tissues or the bones. With second courses there may be temporary tanning of the skin.

Ashbury [14] employs 800 to 1,200 tissue r in four to five weeks and has found no side effects. Much larger doses have been used over growing epiphyses without damaging growth in other locations, for other conditions. Not only have thousands of children been treated for lymphoid hyperplasia but many more for epilation of the scalp for ringworm, and no cases of damage to growing bone or to the pituitary gland from moderate dosage have been reported.

[14] Ashbury, H. H.: Radiation Therapy of Lymphoid Tissue in Nasopharynx and Pharynx, Radiology 43: 250 (Sept.) 1944.

It has been stated that external roentgen radiation causes severe dryness of the mouth. Actually, dryness occurs only with the use of large fields, which involve the salivary glands; these are rarely employed. Since irradiation of the involved tissue may be done with small beams, large fields are not required in the average case. Seedorf and McKay[15] note the occurrence of roentgen parotitis for one to two days after the first treatment, but they use 10 by 10 cm. fields, which, of course, cover a large portion of the parotid. If the lymphoid tissue lying on the posterior oropharyngeal wall or the tonsils are to be included in the ionizing beam, a 5 by 8 or 5 by 10 cm. field should be used, but for cases with the hyperplasia limited to the eustachian areas and nasopharynx, a 6 by 7 cm. field, accurately centered, is all that is necessary; with such fields temporary parotid swelling rarely ensues.

Uhlmann and associates[16] and Schenck[17] have reported microscopic studies made on tonsils and hyperplastic lymphoid tissue removed at various intervals following termination of roentgen and radium treatment; no unwarranted effects secondary to radiation were produced and no changes noted indicating any adverse effects on the tissues. The qualitative histological changes in tissue are identical with comparable doses of filtered roentgen rays or radium rays.

Schenck notes that, prior to radiation, great variety in the cellular structure of the lymphoid tissue is found, and, because of this caution should be observed in interpreting single specimens. The initial changes noted were essentially those of chronic infection and chronic inflammation. After irradiation by radium and roentgen rays, Schenck took serial biopsies at two week, four week and six month intervals. The least change was edema of the follicular structures without desquamation or karyolysis. The maximum finding was swelling of the epithelial cells, with vacuolation and small hemorrhages. There was destruction of endothelial cells. Detachment of ciliated cells was not uncommon. The adult lymphocytes showed little alteration, but the young lymphocytes showed nuclear disturbance or dissolution. The most pronounced changes were in the germinal centers, with liquefaction of many of the cells. Examination after six months showed beginning regeneration, with reappearance of lymphocytes. The germinal centers had not reappeared. There was diminution of fibrous tissue. Often there was no evidence of chronic inflammatory changes.

As to the clinical results of irradiation, it has certainly been shown in thousands of cases that either roentgen or radium therapy can be satisfactory. The dose of radium rays in gamma roentgens must be larger than the corresponding dose of roentgen rays in roentgens to produce similar clinical and histological changes in lymphoid tissue. It must be remembered that the results of irradiation are never immediate but that the changes occur slowly after treatment of one to three months.

Radium Therapy.—The advantage of radium therapy is that it can often be done in the otolaryngologist's office in two or three treatments; however, some cases require a second course (Proctor). Distribution of ionizing energy is adequate if the lymphoid tissue involvement is limited in extent and is not associated with the usual generalized nasopharyngeal hyperplasia.

The disadvantages of radium are several. We have shown the very intense ionization close to the applicator and the rapid "fall off" at a short distance. This means that placement must be exactly on the lymphoid tissue and, further, that only the hyperplastic lymphoid tissue in the immediate vicinity of the applicator receives an adequate dosage. Radium must be used cautiously, if at all, after previous irradiation. It should be used in small doses, or treatment should be deferred, in the presence of severe infection. There is definite danger to the operator on repeated use of radium, and care must be taken to keep his own dosage within tolerance. The beta radiation can be avoided by the use of two pairs of rubber gloves, but the only protection against gamma rays is distance. The physician should stay 30 feet away from the patient once the radium is in place. The radium must be stored in a lead cylinder 4 to 6 inches (10.16 to 15.24 cm.) in thickness and the usual precautions observed in handling it.[4b]

The treatment is not as harmless as generally considered. There have been cases of radium ulcers on the posterior nasopharynx from the above dosages. As noted above, Braestrup estimates that in treating three patients a week permissible tolerance of the hands of the physician or nurse would be reached; therefore, relatives should hold the applicator when such is necessary. Fowler[6] has seen cracked thumb nails secondary to lifting the nostril and inserting applicators. Robbins and Schulz estimate that the operator receives 10 r a treatment at the outer tip of the handle of the applicator; this is quadrupled halfway down the handle. Crowe, on the other hand, states that he has used radon or radium daily for 20 years without any ill effects. Braestrup believes that the regularly employed dose may be productive of late radiation damage to the patient, with ulcers or even neoplasm in the nasopharynx. These changes may take 10 or 20 years to develop.

Robbins and Schulz warn against the routine use of radium or roentgen rays in benign conditions. Postradiation damage may be years in developing, and with the relatively recent use of the radium monel applicator, with its exceedingly high output, late untoward results may occur. These authors suggest the determination of an erythema dose on the arm of the operator and advise that less than an erythema dose be administered in the nasopharynx. As little as 700 r given with mildly filtered radium may produce an erythema of the skin, and some late scarring may follow. With the larger doses routinely employed in the radium treatment of the nasopharynx, the likelihood of atrophy, necrosis or even neoplasia increases.

[17] Schenck, H. P.: Influence of Nasopharyngeal Hyperplasia on Ear: Histologic Examination of Hyperplastic Lymph Follicles After Irradiation, Laryngoscope 51: 780 (Aug.) 1941.

Roentgen Therapy.—The "disadvantage" of roentgen therapy is that it necessitates three to six treatments. There occasionally may be transient parotid swelling and temporary dryness of the mouth if large fields are used.

The advantages of roentgen therapy, as compared with those of radium therapy, are that no anesthesia is required, it can easily be given to children and there is no pain. The centering of the roentgen beam can be exact and duplicated without difficulty. One of the great advantages, as we have shown above, is that the entire lymphoid-bearing area can be irradiated with an adequate dose without harm to the skin, underlying tissues or bones. The weekly dose is only a fraction of an erythema dose. When the roentgen treatment is protracted ionization is more gradual and "gentle" than it is with radium.

COMMENT

The clinical value of radium or roentgen therapy in the control of lymphoid hyperplasia of the nasopharynx has been established over a period of years in thousands of cases. The recognition of the importance of these cases rests with the general practitioner and the otolaryngologist. The realization of the severe consequences of chronic eustachian tube block with resultant deafness and the multiplicity of signs and symptoms of lymphoid hyperplasia should encourage the physician to be alert to detect these conditions and to expose them to safe radiation therapy.

SUMMARY

We discuss the relative advantages and disadvantages of roentgen and radium therapy in the treatment of lymphoid hyperplasia of the nasopharynx that causes deafness and allied auditory disturbances.

We illustrate the distribution of ionization through the involved tissues and adjacent areas, using the two common forms of radiant energy, and we report some recent data on the beta and gamma dosage from standard radium applicators.

In the light of these physical data we show that the dosage throughout the zone commonly involved in lymphoid hyperplasia is more homogeneous and efficient with external roentgen beams than with intranasal radium beams.

We also show that the dose in the immediate proximity of the radium applicators is some 10 times the dose ordinarily regarded as reasonable or safe for the treatment of nonmalignant conditions.

From personal experience in the treatment of 720 cases, we report excellent results with roentgen therapy in from 60 to 90 per cent of the cases, depending on the severity of the disease and the nature of the subjective complaints. These results were validated by independent clinical observation of the referring physicians, many supplemented by audiometric and other objective tests.

The maximum tissue dose required for cure when roentgen therapy is employed is much lower than when standard radium applicators are used: roentgen therapy is consequently safer and should, in our opinion, be employed as the method of choice.

450 Sutter Street.

ABSTRACT OF DISCUSSION

Dr. U. V. Portmann, Cleveland: As stated by the authors, there are reports of ulcerations and other injuries attributed to the radiation from nasopharyngeal applicators. It is possible that not all are due to direct radiation effects but may be the result of injudicious treatment in the presence of acute infection or of unnecessary trauma. Nevertheless, the applicator dosage charts indicate that the quantities of radiation from them at the eustachian orifices are relatively large in comparison with the amounts necessary for destruction of lymphoid tissue or for effectual irradiation of the nasopharynx by roentgen therapy. The particular indication for the radium applicator is for the small masses of lymphoid tissue at the orifice of the eustachian tube or in the fossa of Rosenmüller that cause symptoms. Even this localized treatment, in the presence of acute infection, may be injurious. The reaction to the combination of infection and radiation may result in temporary obstruction to the eustachian tube, causing otitis media, or resulting in later permanent obstruction. Correctly administered roentgen therapy will not cause such damage in the presence of infection. Radium therapy should not be used to destroy large masses of lymphoid tissue in the nasopharynx. The quickest way to eliminate them is surgical removal; roentgen therapy is efficacious, especially if acute infection is present, or postoperatively if there are remnants. Also, roentgen therapy is preferable for primary or secondary enlargement of the lingual tonsils sometimes associated with hyperplastic lymphoid tissue in the nasopharynx. This treatment is indicated for otorrhea, resulting from the same condition, when the eustachian tube is patent yet mucoid material forms in the middle ear. In such cases the eardrum usually is damaged or destroyed. Discussion of the technic for roentgen therapy sometimes leads to unnecessary controversies and may be unimportant. The authors have found "140 kvp with a half-value layer of 9 mm. Al. entirely satisfactory". I was one of the first to prove that biologic effect is independent of quality and that the physical dose applied is of major importance; therefore I consider the voltage and filter unimportant. I prefer 200 kv. therapy because there is less possibility of skin changes and the depth dose is somewhat higher. I prefer to direct the irradiation obliquely through circular portals over the maxillary antrums. The distance from these portals to the orifices of the eustachian tubes is the same (about 6 cm.) as it is through the lateral portals used by the authors. The entire nasopharynx can be treated by angulation through small maxillary portals and irradiation of the parotids, teeth and temporomandibular joint is avoided.

Dr. Henry J. Ullmann, Santa Barbara, Calif.: I want to add one more point that Dr. Portmann left out. How many of these children receiving this relatively massive local dose of radium are going to turn up with atresias, fibrotic areas or late radiation breakdowns, one, two, three, four, five or six years later? And the physician who sees them has never heard of their having had radium, and wonders how he is going to account for it. There are late effects that are extremely important, and I am frankly much worried at the percentage of those that will occur after the recommended dose of radium but will not occur with properly given roentgen ray therapy.

Dr. John O'Sullivan, Melbourne, Australia: I should like to congratulate the speaker and the co-authors of the paper. I should like to ask only one question. In the presence of severe infection, does Dr. Mottram in any way modify the dosage administered, especially in the early cases? I have personally carried out this method, and I start off with a much smaller dose; I am just wondering whether she has in any way found that necessary.

Dr. Martha E. Mottram, San Francisco: We prefer to have the otolaryngologist try to clear the infection in the nasopharynx. Otherwise, if we start radiation therapy, the dose is cut down, and, of course, with radium therapy in acute infection treatment should be deferred or it should be cut down very considerably.

Chairman: You said the radium therapy should be cut down?

Dr. Mottram: Or deferred.

Chairman: But you have not had any difficulty with the use of roentgen therapy in cases that have shown infection?

Dr. Mottram: No, we have cut our doses, but we prefer to have the infection cleaned up first if it is severe.

SPECIAL ARTICLE

BENIGN AND MALIGNANT DISEASES OF THE BREAST

Edward J. McCormick, M.D., Toledo, O.

From time to time there will be published in THE JOURNAL *review articles intended for the general practitioner. Dr. McCormick's article is one of this series.*—ED.

Many of our ideas regarding breast tumors and cancer and the results of treatment are misleading for various reasons. Surgeons generally are inclined to speak of breast operations in numbers that far exceed the incidence of breast cancer in the experience of the individual operator. A recent survey at one hospital, where I participated in a heavy surgical schedule (7,059 operations in 1949 and 7,032 in 1950) and where admissions to all departments average 13,000 a year, showed that 129 breast specimens were examined in 1949 and 99 in 1950. Of the 228 biopsies done, 59 were on adenocarcinomas. A similar ratio has been found to exist in other large general hospitals in communities of 200,000 or 300,000 inhabitants. There is, of course, no doubt that some surgeons in a few centers, who have devoted themselves in large part to breast surgery, have operated on large numbers of patients with breast cancer, but this is not true of the average general surgeon. The busy operator will be surprised if he reviews his last 10,000 operative procedures to find that he has done comparatively few radical operations for breast cancer.

Adair[1] states that breast cancer is the commonest type of cancer found in women, and he notes that in New York state there are 60 women per 100,000 population in whom breast cancer develops or one new breast cancer develops in women annually to each 1,666 of the population. This means, according to Adair, that in a city of 100,000 population not more than 60 new breast cancers would develop in a year. The probability that a woman will acquire cancer of the breast is higher than the probability that the same woman will acquire cancer of the cervix, uterus or ovary, according to a survey made by the Bureau of Cancer Control of New York state in 1948 and cited by Adair. These figures would be found true in the average community. In a city of 300,000 population 180 cases in a year divided among the qualified operators give each surgeon few cases and the occasional operator little experience in this field. It has been estimated that 12,000 women die each year in the United States from breast cancer. It has been said that about 4 per cent of all female adults acquire the disease.

I think it can also be stated that the various prognostic classifications of breast cancers are faulty. The fact that the patient has a small movable tumor and no palpable axillary nodes does not necessarily place her in a group in which 80 per cent or more cures may be expected. Distal metastases may be present. Unless a more diligent search by x-ray and physical examination is undertaken, the family, the patient and the surgeon may be disappointed. It is also true that the larger tumor with some fixation and palpable axillary nodes may still be localized in the breast and axilla.

No statistics dealing with results of radical breast surgery should be based entirely on the so-called five year cure. Cancers do recur 10, 15 and 20 years following radical mastectomy. Five year salvage is not permanent cure.

Examinations of breasts are being conducted by physicians and patients more frequently because of publicity and information reaching the laity. Biopsies are increasing in most hospitals. Prevention is always superior to attempted cure. More radical treatment of questionable benign and so-called premalignant conditions should be considered. I see no reason for too much conservatism in management of so-called chronic cystic mastitis, in which a local biopsy removes only a small part of a disseminated condition that is frequently painful and considered by many as chronically irritating and capable of undergoing malignant change. There are opinions to the contrary. Some experienced men have said, in effect, that so-called chronic cystic mastitis will subside with the menopause. This may be true, but the real answer as to what a physician should do in such a case is obvious if he has as much concern for the patient as he would have for his mother, wife or sister.

In my experience, the type and location of the growth and the age of the patient are perhaps more important than the size of the mass or its movability.

The connection between breast tumors and endocrine activity deserves continued study, and this is especially true so far as replacement therapy is concerned. While it is said that cancer of the breast can be caused by administration of estrogens in the experimental animal but not in the human, the prolonged administration of certain preparations causes changes in the female genital tract and in the breast. This is especially true of the too ambitious use of diethylstilbestrol (premarin,® a water-soluble estrogenic substance) and other products. If this type of therapy is necessary, the patient should be under observation and the breasts should be examined at frequent intervals.

Testosterone has a definite place in the treatment of breast cancer. One of my patients, with bone and soft tissue recurrences, pathological fractures of several ribs and fluid in the pleural cavity, requiring thoracentesis on three or more occasions, has shown no recurrence after testosterone therapy. Seventeen thousand milligrams has been administered by implantation and by injection. The result has been amazing. Other patients have responded in degrees that could be described as good, fair and poor. It is astounding to me that cancer of the breast can present so great a variation of response to all forms of treatment and to all combinations of recognized surgical and therapeutic measures. I have seen cases in which testosterone propionate had no effect. Some patients have seemed to improve to a degree after cessation of treatment. Estrogens have been used. My observations of the efficacy of female hormones have been limited and the results not impressive. I have been enthusiastic in my use of testosterone, but extremely cautious in my use of estrogens, in breast cancer. I have felt at times that patients with breast disease who return to their homes after surgery and radiation should be warned against female hormone therapy unless it is administered by someone expert in the field of cancer. George Crile's statement years ago that sterilization of the breast cancer patient seemed helpful, and the subsequent observation by others that orchidectomy and diethylstilbestrol treatment were indicated for cancer of the prostate gland and testosterone therapy for the improvement of some patients with breast cancer—both impress me with the fact that there are powerful extracts and drugs whose complete potentialities may not be understood. The endocrine glands and substances present a rich field for the researcher in cancer. In this connection, reports have reached me concerning the development of gynecomastia and breast cancer in patients with prostate disease who are on diethylstilbestrol therapy. One such patient has been operated on recently by one of my colleagues.

---

[1] Adair, F. E.: Practitioner **165**: 473-481, 1950.

I have removed many benign tumors and some carcinomas from male breasts. The results of treatment of cancer of male breasts are very poor.

I have no hesitancy in advising surgical or x-ray castration in the child-bearing group. Cancer of the breast in young women and in pregnant women has pathological potentialities, I have found, which might be compared to the physical powers of the atomic bomb. Pregnancy is a stimulator of cancer of the breast or the cervix. The most rapidly fatal cases in my series have been among the younger patients with active gonads and pregnancy.

No consideration of the breast is complete without some understanding of the profound changes occurring in the organ from birth and through puberty, the menstrual periods, pregnancy and the atrophy of old age. The female breast is in a constant state of activity. These changes are physiological, and they are hormonal in origin. The physiological, embryological and hormonal influences on the male and female breast are important in the interpretation of pathology and the treatment of all breast lesions whether benign or malignant.

EMBRYOLOGY

About 55 years ago Schultz (cited by Fitzwilliams [2]) demonstrated epidermal ridges extending from the axilla to the groin in early pig embryos. These lines became separated into epidermal elevations as age advanced. This line is well developed in the human embryo 15 mm. long, and it segments when the embryo is 26 to 60 mm. long. These areas were called *Anlagen* by the Germans and milk spots by the English. The embryonal development of the breasts, therefore, makes possible many anomalies. Among these are (1) inverted nipples, (2) amastia (absence of the breasts), (3) polymastia, (4) hypertrophy, (5) polythelia, (6) gynecomastia and (7) athelia (absence of the nipple).

Of special interest in the anomalous group is polymastia, the multiplicity of mammary glands, which presents the possibility of primary breast tumors in the axillas, the abdominal wall, the groin and the thighs or buttocks. Breast tissue may be found in these locations with athelia or absence of the nipple. Hypertrophy is sometimes difficult to distinguish from malignant degenerative changes. It is a surgical condition, incident in both young and old, and it can occur in any decade of life after puberty.

Breast development in the male should be observed at frequent intervals and especially in patients on hormone therapy. Any deviation from normal in the human breast makes possible the appearance of unsual pathology.

There are certain conditions in the breast that, while not malignant, should be clinically considered so until proved otherwise. Among these are (1) adenomas or fibroadenomas, (2) myxomas, (3) chondromas and osteomas, (4) angiomas, (5) chronic mastitis and chronic cystic mastitis and Schimmelbusch's disease, adenosis.

Adenomas, once their capsule is ruptured, may become infiltrative if not malignant. Fibroadenomas are hard, encapsulated, freely movable tumors. Some intracanalicular fibroadenomas have been known to grow rapidly, producing skin necrosis and forming an ulcerating mass.[3] Myxomas, chondromas, osteomas and angiomas are very rare and do not become malignant.

I have previously referred to chronic mastitis or chronic cystic mastitis. This condition seems difficult to distinguish from adenosis. Perhaps these terms designate different states in one pathological condition. Contrary to the views expressed by some other experienced men, I am of the opinion that this condition may be precancerous. Everything necessary for chronic irritation is certainly present. A cancerous change has been found in or subsequent to chronic cystic mastitis. It has been said by Behan [4] that the greatest number of adenocarcinomas arise in the walls of the papillary growths of cysts in chronic cystic mastitis. It has been my practice, when I do a biopsy for a breast lump, and when, in removing the suspicious area, I find the tissue of the breast permeated with dark cysts of varying size, to proceed through a small incision to remove all or most of the breast tissue. Leaving such breast tissue when the frozen section is negative is an invitation to future trouble for the surgeon and continued complaint of lumps and soreness and mental disturbance of the patient.

Cysts of the breast may be classified as (1) simple, (2) galactocele, (3) fibrocystic adenoma, (4) papillomatous and (5) echinococcus.

[3] Bevan, A. D.: The Problem of Tumors of the Breast from the Standpoint of the General Practitioner and Surgeon: Diagnosis, Treatment, Pathology and Prognosis, J. A. M. A. 95: 1311 (Nov. 1) 1930; also, Proc. Internat. Assemb. Inter-State Post-Grad. M. A., North America 5: 140-146, 1930.

[4] Behan, A. D.: Cancer, St. Louis, C. V. Mosby Company, 1938, p. 159.

Cancer has been found in cysts of the breast. All cysts should be removed for examination by the pathologist. In connection with chronic cystic disease and cystic adenoma, let us recall that Ewing [5] has pointed out that papillomas or cystic adenomas may be benign as long as the intracystic growth is confined by the cyst wall. When the capsule is penetrated, the growth is definitely malignant.

CANCERS OF THE BREAST

Cancer of the breast may be classified as (1) scirrhus carcinoma, (2) adenocarcinoma, (3) ductal carcinoma, (4) medullary carcinoma, (5) epithelioma, (6) Paget's disease, (7) sarcoma and (8) metastatic neoplasm.

These tumors are all surgical if the diagnosis is early, and there is hope for cure. Surgical palliation may be necessary in certain advanced cases. It is my practice to advise the patient and the family as to what may be expected in the way of cure or palliation. Frank discussion of all probabilities results in better cooperation with the surgeon and radiologist and likewise informs the patient and her family regarding the limitations of the various modes of treatment. When the tumor is classified as to operability and prognosis from the standpoint of the breast and axillary findings, x-ray studies of the bones of the head, neck, chest and trunk are helpful. Positive findings may contraindicate a radical procedure and protect the surgeon and his art from criticism. The discovery of distal metastases will change the surgical and radiologic procedures.

Much confusion exists concerning the pathologic classifications and character of papillary neoplasms of the breast. The two types of papillary neoplasms are the benign intraductal papillomas and the malignant papillary carcinomas. The first type is frequent. The malignant type is rare according to some observers, but other operators have observed an incidence of malignancy of 47.2 per cent in cases in which there was sanguineous discharge from the nipple.[6] Bloodgood concluded many years ago that serous or bloody fluid, in the absence of a palpable tumor, did not indicate cancer. Haagensen, Stout and Phillips advise local excision of the duct and papilloma in the nonmalignant type with a reasonable margin of surrounding breast tissue.[7] If the papillary neoplasm is malignant, radical breast surgery should be done.

PROGNOSIS AND OPERABILITY

The type of cancer cell, the age of the patient and other factors influence operability and prognosis. The following classification, not original with me, has been presented with variations by numerous authors:

1. If the breast contains a small movable tumor and no palpable lymph nodes and there is no evidence of intrathoracic or skeletal metastases, a minimum of 70 per cent of the patients should be alive and well five years after radical surgery, 71 per cent if postoperative radiation has been given. Some authors state that under these conditions 80 to 90 per cent should survive for five years. The point that interests me and all patients is the percentage in this group in which the disease is entirely eradicated and permanent cure possible. All classifications indicate that from 10 to 30 per cent are not alive in this, the most favorable group, after five years. Some of course, die from causes other than cancer.

2. If there is a large tumor in the breast with fixation to the skin or to the pectoral muscles and palpable and microscopic evidence of axillary metastases, 28 per cent of the patients with such manifestations will be alive in five years following radical surgery and 57 per cent will be alive for this period if radical surgery is followed by radiation.

3. Patients with axillary and supraclavicular nodes and distal metastases can be offered little hope. With radiation, 5 per cent or less may live five years.

It is evident, as previously stated, that this and other similar classifications of breast tumors for prognosis are faulty. The curability figures given by different authors vary, and surgeons and radiologists frequently differ in their opinions regarding the classification into which a given patient should be placed. I have seen patients who were treated early promptly develop metastases, and I have in my own practice seen patients who were in class 2 living and well years after surgery and radiation. The pathological picture and the age of the patient are probably the most important factors and should supersede other considerations.

SYMPTOMS OF BREAST CANCER

Every paper and textbook describes and lists the symptoms of cancer. MacCarty [8] has said, "Cancers are not recognized early by the medical profession and never will be until it learns that there are no characteristic signs and symptoms of early cancer."

A history of hereditary influences, trauma, abscess formation, caked breasts, pain and absence of pain, itching, orange peel appearance of the skin, abnormal superficial vein pattern, change in contour and other signs and symptoms are of value, though some are evidence of advanced growth. I prefer to tell my colleagues and patients that "every lump in the breast is a cancer until proved otherwise." Transillumination is impressive but of limited value. I am not an advocate of aspiration of cysts or needle biopsy. Careful and proper examination of all breasts, both male and female, and biopsy of any suspected area offer more to the patient and doctor than do any other procedures. I have not been satisfied with results obtained by the Papanicolaou examination of fluid from the nipple. In this connectoin, removal of a lump or part of a lump from a breast, followed by surgery a week or two later, is the worst possible treatment in the light of our present knowledge.

We hope, of course, that our research workers will develop a technique wherein the Geiger counter may be of value in breast examination and diagnosis. It is my opinion that the doctor or surgeon should forget textbook descriptions and symptoms and resort to biopsy when a lump is found in the breast.

Biopsy, removing by a good margin the mass in the breast, and frozen section by a capable pathologist should be followed immediately by radical mastectomy if cancer is discovered. All instruments, gowns, gloves and drapes used in the biopsy procedure should be discarded before the major operation is started. Pathological breast tissue cannot be removed without cutting across drainage channels, which in cancer cases probably contain malignant cells that may be transplanted.

The operative technique may vary in radical mastectomy, but regardless of whether a transverse, Halsted or other incision is used, a complete dissection of the axilla should be done and all tissue from the axilla reflected downwards with the pectoral muscles and fascia extending to the rectus sheath. No approach should ever be made for convenience of closure. Skin graft may be necessary on occasion.

The radical surgical treatment is being widened in scope in some centers to include resection of the clavicle and dissection of the neck glands, and removal of involved ribs and of the axillary vein has been advocated. Additional experience with the extension of surgical attack may change to some extent the accepted routine of radical mastectomy, but it seems logical to believe that the large percentage of patients requiring such additional surgical attacks have already developed distal metastases.

Simple mastectomy followed by x-ray therapy is advocated by some and is mentioned only to be condemned. It should also be stated that there is no longer debate regarding the respective merits of surgery and x-ray therapy. The statistics plainly show that x-ray therapy alone is of limited value. Some good surgeons feel that no case of cancer of the breast is cured except by complete surgical removal. I agree with these competent and experienced operators, but my patients all have postoperative therapy because results are improved and one can rarely be certain in cancer surgery that all cells have been removed, regardless of the skill of the operator or the extent of the excision.

SUMMARY AND CONCLUSIONS

In closing, permit me to emphasize some of the important points to be considered in breast cancer.

The breast is one of the most accessible parts of the human anatomy. Examination is simple. Breast pathology should be recognized early by the practitioner if results are to be improved.

Biopsy is the only reliable means of establishing the diagnosis.

The age of the patient and the type of breast cancer are most important in the determination of prognosis.

Complete excision of the breast and axillary contents is absolutely necessary if cure is expected. Operation should be followed by expert radiological treatment.

Early diagnosis and radical mastectomy seem more important to me than extension of the surgical field to the neck, thoracic cage and other structures. Such extension presupposes wide distribution of the disease beyond the scope of the aseptic scalpel.

The endocrine field seems to offer much to the research worker and to the breast surgeon. There is little doubt in my mind at the present time about the possibility of direct relationship between malignant development in certain parts of the male and female anatomy and endocrine activity.

A revision of the accepted preoperative and postoperative yardsticks, having to do with operability, prognosis, five year cures and permanent cures, seems indicated.

This paper and the conclusions contained therein are the result of the examination of thousands of breasts and hundreds of operations upon the breast for benign lesions and malignancies. There seems to be a tendency in the literature today for an ultrascientific appoach to breast lesions. I have never been able to convince myself that catheterization of the ducts, injection of opaque material and other suggested procedures are of great importance. It is my opinion that early biopsy and early operation, when indicated, will improve results, and it is also my belief that the removal of benign lesions will frequently prevent the development of cancer. In my experience, mortality following radical breast procedures, when ample blood replacement is used, is practically nil. I have had but one death among my last 300 patients. I am concerned with the problem of permanent cure. My percentage of permanent cures is in line with the experience of others who do much work in this field. I am always depressed, as is every breast surgeon, when metastasis develops in the so-called early case.

The approach to the treatment of all cancers will change during the next 25 years. The cure will not be within the scope of our present techniques. It will be simplified. It is my hope that the youthful cancer sufferer and those of more years, in the so-called cancer age, will be protected against cancer or, if afflicted, promptly cured. This hope is common to all of us. We have made progress in our attack upon benign and malignant lesions of the breast, but we have a long distance to go and we will have more opportunity of reaching the millenium when we recognize the limitations of our present mode of attack on both the early and late cases.

Advice on Diet.—The fundamental principles of medical dietetics are only slowly emerging from an accumulation of scientific data on one hand and a mass of traditional empiricism on the other. Just as the paramount importance of good nutrition in the maintenance of health has become more widely appreciated by medical men in recent years, so the prescription of complicated diet sheets has tended to recede into the background. There can be few instances in dietetic out-patient departments in which the giving out of printed diet sheets is justifiable. Advice on diet should be individual and not done by routine mass-methods, and even in individual cases the actual writing out of detailed diet sheets should rarely be necessary, with a few obvious exceptions. The primary object of a dietetic department should be to spread the gospel of sound nutrition among the population, and the dietetic treatment of various diseases usually only calls for very simple common-sense advice. Yet 15 years ago it was commonly believed by medical men that there was some specific dietetic treatment for a large number of disorders, for which detailed diet sheets were supposed to have an almost mystical therapeutic potentiality.—D. M. Dunlop, Modern Trends in Therapeutic Dietetics, *The British Journal of Nutrition,* Vol. 4, Nos. 2 & 3, 1950.

COUNCIL ON NATIONAL EMERGENCY MEDICAL SERVICE

This paper is one of a series requested by the Council on National Emergency Medical Service to inform the medical profession on problems pertaining to civil defense. It does not necessarily reflect, however, the opinions of the Council or any other official body unless so stated in the article.

C. JOSEPH STETLER, *Secretary.*

RADIOLOGICAL ASPECTS OF CIVIL DEFENSE

George M. Lyon, M.D., Washington, D. C.

GENERAL CONSIDERATIONS

Should there ever be an atomic attack on this country, the public generally would want something done to ascertain whether there was any danger from radioactive contamination. They would probably not be satisfied unless this were done, and they would probably blame the responsible authorities in local government if it were not done. The assurance that radiological surveys had been carried out, and that they revealed no danger from any residual radioactive contamination, would probably go far toward reducing confusion and perhaps even minimizing that phase of a tendency to panic which may be based on fear of radioactivity.

It is difficult for the person who is not technically trained to understand the phenomena of radioactivity. It is difficult for the average person to visualize the significance of radiological hazards because they are not readily detected by the senses, their presence being made known at the time only by the use of special instruments. Unseen, unheard and not felt, they tend to fall into the category of the "unknown," and fear of the unknown is often more difficult to control than fear of the known. Because of this, and various other factors, the role of radiological safety personnel in the prevention or control of panic could be of vital importance in event of atomic attack. Information they can collect and interpret will have a very important bearing on a variety of problems involving human psychology and human behavior, problems which are of primary concern to the responsible authorities of civil government in event of atomic attack.

Definition of Radiological Defense.—Radiological defense is defined as the protective measures taken to minimize personnel and material damage from radioactivity resulting from enemy attack. As such, it is a planned, organized and directed scheme of "radiological safety" which includes more than simple detection and measurement of radioactivity. It includes as well:

(*a*) Training, organization and distribution of technically qualified personnel.

(*b*) Development and application of techniques and procedures of radiological safety, including the use of instruments for detecting and measuring activity to the end that, as a health protection measure, the existence of residual radiation hazards can be determined and their significance estimated.

(*c*) Development, provision and maintenance of suitable technical equipment.

(*d*) Protection or removal of exposed personnel.

(*e*) Decontamination of personnel, equipment, structures and terrain.

In civil defense, radiological defense is the organized effort of the people, acting under civil authority, to prevent or minimize the injurious effects which may result from the exposure of personnel to residual radioactivity, or "radioactive contamination," which may result from, or arise in connection with, an enemy attack on civil populations.

Radiological defense measures would be particularly directed against the radioactive contamination that might exist after the detonation of an atomic bomb. They would be equally effective, however, if an enemy deliberately employed radioactive materials as an offensive weapon against civilian populations.

Aims of Radiological Defense.—The more specific aims of radiological defense within civil defense are (*a*) to prevent or minimize confusion and panic, through collection and proper dissemination of factual information concerning the existence, or nonexistence, of radiological hazards, (*b*) to prevent or mitigate personnel injuries resulting from exposure to residual radiation hazards, through detection and avoidance of such hazards and (*c*) to facilitate the work of relief and the restoration of essential community services, through the protection of personnel whose civil defense duties require their entry into radiologically hazardous areas.

Some Problems in Radiological Defense.—What are some of the special problems of radiological defense? There are a variety of such problems. Many of these are technical in nature. They are probably the easiest to solve. Others relate to the difficulties of organization and preparation of a special group of civil defense workers and the development of effective civil defense operation schemes. These are probably the most difficult to solve. Still others are intimately related to difficult problems in human relations and in human psychology and behavior.

Requirements in Radiological Defense.—General requirements may be summarized briefly.

A national policy with respect to radiological defense is required and has been established.[1] In line with this policy, a plan or scheme for radiological defense must be prepared in certain states and communities.[2] An organization must be developed to carry out the plan. Qualified personnel will be required to implement the plan. Persons who are proficient in the detection and measurement of radioactivity must be trained to apply these techniques in civil defense and in civil defense operations.

Instruments of the proper type and in appropriate numbers must be procured and made available for radiological defense personnel. These instruments will be needed for training as well as in event of an emergency. Instruments must be carefully selected and suited to the needs and requirements of civil defense activities.[3] Provisions must be made for their issue, storage, maintenance and repair. They must be appropriately dispersed and kept in a state of functional readiness.

Radiological defense personnel will need to be trained to work with personnel in other civil defense activities. They will also be needed to assist in the instruction of workers in other civil defense services, and in the interpretation to them of information concerning radiological safety measures. Some qualified radiological defense personnel will be needed to serve as radiological safety advisers on the civil defense staffs of mayors and governors.

Radiological defense specialists will be required to meet and solve some of the more complicated or "postgraduate" technical and scientific problems which may arise, particularly those associated with the prevention of radioactive poisoning and the evaluation of hazards that may give rise to such poisoning. Qualified radiological defense leaders will be needed to provide for the benefit of the public, reliable information relative to the existence or nonexistence of radiological hazards and to interpret their significance if present.

Ability to cope with atomic disaster will depend in large measure on the state of preparation for civil defense that exists at the time of the attack. This state of preparation, in turn, will depend on the preliminary training that has been conducted, the organization that has been effected and the civil defense forces, including those for radiplogical defense, which are "in being" at the time of attack.

A general understanding of the phenomena associated with the explosion of an atomic bomb and the effects produced by such an explosion is essential for those directly concerned with radiological defense planning. A technical treatment of those matters,

---

This is not an official statement of any agency of the federal government.

however, does not lie within the scope of this discussion except insofar as may be required later to explain the specific problems in hand.

Radiological defense will employ a technology new to civil defense but one that has been successfully applied in the various atomic bomb tests that have been conducted. It involves intelligent and sound application of technical and scientific knowledge, some, but fortunately not all, of it highly specialized. The radiological defense organization will be composed of technical personnel who have not been medically trained. They will serve a health protection service. In this, they will bear a very important relationship to the medical services and to the broad medical mission of civil defense.

Technical information obtained by radiological defense personnel will permit qualified and specially trained medical officers of the civil defense organization (1) to make a medical evaluation of the situation (2) to interpret the medical significance of such radiation hazards as might be encountered and (3) to evaluate such individual exposures to radioactive contamination as may be required by the mission of the medical services. The Radiological Defense Advisory Committee may, to advantage, serve in the capacity of a Radiation Evaluation Board if this is deemed locally practicable.

While it is desirable for all physicians to have some general knowledge of the purposes of radiological defense and to know in general how the radiological defense mission is accomplished, physicians should not serve as monitors. This would be a serious waste of greatly needed medical personnel. Although not needed in great numbers, some physicians would be required who have had some special training to enable them to serve as advisors in the medical phases of radiological defense. In like manner, scientists and highly trained technical personnel should not ordinarily serve as monitors on radiological defense teams. A limited number of such personnel would be vitally needed, however, to serve on radiological defense "specialists teams" in connection with some tasks which are technically more difficult and more complicated than that of radiological survey work and monitoring.

Qualified radiological defense personnel, possessing level heads and exercising sound judgment, can be of invaluable assistance to civil defense leaders and can do a great deal in the public interest. Careless, or poorly qualified, they can be very harmful to the public interest. This fact and its importance must be recognized at all times. It is essential that radiological defense leaders possess not only sound technical qualifications but a level head and the ability to exercise good common sense as well.

Radiological Defense in Action; Attack and Actions Assumed.—Radiological defense personnel would have a variety of duties. The importance of these duties in relation to civil defense would vary in accordance with the conditions that would be found to exist after an attack. They would also vary somewhat with respect to the time that may have elapsed subsequent to the attack. In most instances it is likely that need for such personnel would be greatest immediately after the attack and perhaps for a day or two thereafter. Should no residual radiological hazard exist, once this fact is known, relatively few radiological defense personnel would be needed in the incident area. They would then be available for other civil defense duties. Should there be a significant residual radiological hazard, the number of personnel required and the duration of the time that they would be required would be greater depending on the conditions encountered.

A clearer understanding of the problems of radiological defense may be developed, if the situation likely to follow an atomic attack be assumed and certain proposed radiological defense measures described.

A. Early Phase, Before Civil Defense Headquarters Is Established: In event of attack, community authorities, in accordance with a prearranged plan, would undoubtedly issue a "call to duty" for civil defense personnel. Radiological defense personnel would report to some suitable and prearranged "reporting in" place (police headquarters, fire headquarters, offices of health departments, training centers in local schools) and await further instructions.[4] Their movement from there into the area of civil defense activity would be in accordance with the needs of those in charge of the civil defense work. Those persons most readily available, and nearest to the incident, would be employed to assist "on the spot" commanders of the police and fire services. Personnel to conduct radiological surveys of the area[5] would probably have to be aided by the police or fire services through their provisions of (1) emergency transportation and escort and (2) emergency communication services. Once at the site of the incident, radiological defense personnel would carry out a radiological survey. If any radiation were detected, it would be measured and the significance of the hazard evaluated. Should radiologically hazardous areas be found, the existence and location of such hazards would be made known to the responsible authority (police) within the area, their specific boundaries would be delimited and their significance indicated. The police, not the radiological personnel, would be responsible for the control of the movement of persons into and out of a hazardous area.

As soon as possible, information relative to the radiological hazards would be communicated to central civil defense control, in accordance with a prearranged plan, preferably through police or fire service communication facilities. On the reliability and availability of this initial information may well hinge the effectiveness of all early phase civil defense operations.

Personnel of the radiological defense organization not engaged in area survey work would be assigned as "service monitors"[6] to accompany working parties of the fire and rescue services. Their duty would then be to remain with these parties, insofar as practicable, to advise them of the severity of the exposures, if any, to which they might be subjected while carrying out their work and to give technical information to "on the spot" commanders essential to the calculation of such risks, with respect to radiological exposures, as might be required. Their aim would be to prevent such injurious overexposures as might not be reasonably justifiable. It would not be to prevent persons from accepting such risks as are justifiable. A practical example may be given. If a serious overexposure could be incurred by a group of men working in a hazardous area for eight hours, a moderate exposure in four hours and an insignificant exposure in two hours, there would be little justification for permitting the eight-hour exposure. A replacement of the group at the end of four hours or earlier would be most desirable from the standpoint of human values and economy of manpower. It would also be practicable even in civil defense work. The requirements of radiological defense must not be intended to prevent exposures that are really necessary. They are to prevent those injurious exposures that are not really necessary.

B. Early Phase, After Central Civil Defense Control Is Established: As soon as a central control of civil defense is able to function with respect to personnel working at the site of the incident, central control could receive emergency radiological reports from leaders of survey personnel via police or fire service communications in accordance with prearranged plan. By this means, the responsible authority in the city would be advised as to the nature, extent and seriousness of radiological hazards present as tentatively indicated by earliest reports of the radiological survey of the area. This is a vital "intelligence" function. Should it be found that no significant or extensive radiological hazards exist, the conduct of fire, police and rescue operations could go on as rapidly as other conditions would permit and without the need of observing radiological safety precautions. Radiological defense personnel would then be held in reserve areas and should not be moved to the area of destruction except as specific need might arise, at which time they would be sent out by authority or direction of the local civil defense commander. The information gained by the radiological survey operations in this early phase would be of great importance to the conduct of civil defense operations after this time. A limited number of radiological survey personnel would continue to make surveys to confirm or alter the earlier estimate of the situation with respect to radiological hazards.

If radiological hazards were found to exist, and if they were of sufficiently serious physiological significance, the civil defense operations might need to be conducted with somewhat more caution. Life-saving rescue work would undoubtedly be done in most instances regardless of the hazards. The technical information obtained from the radiological survey of areas would provide the basis for the evaluation of the hazard and for the preliminary calculation of the risk that might be incurred. Information of this character would be required (1) for those responsible for directing civil defense activities, (2) for group leaders and (3) for the guidance of the individual civil defense worker.

---

[4] At such places instruments for radiological survey could be suitably dispersed and stored so as to be available to the radiological defense personnel when needed. Such a plan would make possible the assembly of personnel at places where teams could be organized and where they could obtain necessary equipment.

[5] Vide infra Area Survey Teams, under Organization.

[6] Vide infra Service Monitoring Teams, under Organization.

Personnel of the fire and rescue services, when required to work within the radiologically hazardous area, could be accompanied insofar as practicable, by "service monitors" of the radiological defense organization. They would, in general, be attached to these services at the time, rather than prior to the attack. If so, it would be their duties to measure the exposure of individual working groups and to advise the responsible group leaders, and "on the spot" commanders concerned, as to the nature and severity of the risks being encountered or assumed. Only in exceptional circumstances would it be necessary to report this information back to sector control centers and central civil defense headquarters.

If the radiological hazards were slight, or of no significance or if they were absent, the presence of some radiological defense personnel with these working parties, or at least their ready availability, would do much to aid the morale of the civil defense workers and do much to offset the adverse psychological effects that might be expected.

If there were a significant residual radioactive contamination, such protective services would be of vital importance in the avoidance of important and injurious overexposures of civil defense workers and of other personnel.

C. Later Phases, Under Central Civil Defense Control: Should there be no residual radiological hazards, relatively few radiological defense personnel would be required to continue on duty after the first day or so, although a skeleton organization should probably be maintained, particularly to make checks on areas suspected of being, or rumored as being, radiologically hazardous. If there were significant residual radiological hazard, then the services of the radiological defense personnel might be needed for some days or longer, and an extended radiological safety operation would probably have to be carried out.

During the conduct of the activities just described for the three phases of civil defense operation, it would be necessary to maintain a radiological situation plot in the civil defense headquarters and the main subordinate control centers. On such plot-maps would be charted information concerning the location and the severity of the radiological hazards. This information would be required for the use and guidance of those in responsible authority within the community. Information could be passed from leaders or groups conducting radiological survey in the field to the subordinate control centers by way of police service communications and/or fire service communications, or by such other means as the civil defense plan may provide. Subordinate control centers would communicate with central headquarters.

The police and fire services are normally prepared to utilize all forms of modern communication and have personnel skilled in their use under conditions of disaster. They also have alternate facilities to use if needed, including even motorcyle and foot messenger services. While it would not be practicable to send routine radiological defense information via police and fire service communication facilities, the civil defense plan should, nevertheless, assure the availability of these facilities for high priority and emergency reports.

In the very earliest phases of the incident, the transportation of essential radiological defense personnel up to, and within, the incident area would present a problem that must be provided for in the operation plan. Police or fire forces personnel might be required for escort. It would be necessary to have some workers among the radiological defense personnel who would be concerned with instrument supply, replacement and repair.

Other aspects of radiological defense operations in areas removed from the immediate site of destruction include the problems that may arise in connection with suspected "downwind" air contamination and "fall out" resulting from atomic attack. These will be discussed later.

TECHNICAL CONSIDERATIONS IN RADIOLOGICAL DEFENSE

Radiological Hazards Produced by Atomic Attack.—The detonation of an atomic bomb can, and may, produce two general forms of radiological hazard, the occurrence and importance of which would depend largely on the manner in which the bomb was detonated, that is, whether high in the air as at Hiroshima, near the surface of the ground as in New Mexico and at Eniwetok or under water as at Bikini. There are two general types of radiological hazard which might be created: (*a*) initial radiation hazard and (*b*) residual radiation hazard.

Initial Radiation Hazard.—The initial radiation hazard is created by the prompt radiation of gamma rays and neutrons at the moment of detonation and by the delayed radiation of gamma rays and neutrons from the "ball of fire" immediately after the detonation and lasting for a period of not more than two minutes thereafter. The initial radiation is the severest external radiation hazard created by the explosion of the bomb. The initial radiation hazard produces injury only as a source of external body radiation.

At Hiroshima some persons were by chance shielded by terrain, earthen embankments, heavy concrete walls or similar barriers to gamma radiation. Some who had taken refuge in underground shelters at the time of the air raid warning and who remained there were protected from the injurious ionizing radiations. It is difficult to plan for protection against this radiation hazard. Because protection against the initial radiation hazard is not a function of radiological personnel, this problem will not be discussed in greater detail at this time. It is well, however, to point out that suitable advice relative to this problem is being provided the states by the Federal Civil Defense Administration.

Residual Radiation Hazard.—A residual radiation hazard may, under certain conditions, result from the explosion of an atomic bomb. A hazard of this nature may be due (1) to the presence of fission products that are produced by the splitting of atoms in the bomb explosion and emit beta particles and gamma rays, (2) to the presence of unfissioned bomb material (plutonium) or (3) to the presence of radioactive materials resulting from the bombardment of certain chemical elements by neutrons at the time of, or immediately after, the detonation of the bomb. A residual radiation hazard may cause injury (1) as a source of external radiation or (2) as a source of internal radiation.

Protection against the residual radiation hazards is achieved by the employment of radiological safety measures. The hazards can be detected and their significance evaluated. They can, in large measure, be avoided. The organized and directed activities of radiological defense personnel are aimed primarily at the prevention of injuries from residual radiation hazards.

The gamma radiation from residual contamination can be severe but will not approach the intensity of that of the initial radiation. After the first day or so it would be difficult for one to acquire a severely injurious overexposure to penetrating gamma radiation, or even a dose in excess of 100 of total body radiation.

Radiological Hazards of Various Types of Bomb Bursts.—*Air Burst:* The detonation of an atomic bomb at the altitude employed at Hiroshima and Nagasaki would produce an intense initial radiation hazard. The bomb would produce the same effects as were observed in the victims at Hiroshima and Nagasaki. The radiation injuries produced in the survivors at Hiroshima and Nagasaki were all due to this form of hazard. Gamma radiation alone was responsible for all radiation injuries that occurred in persons who were more than a few hundreds yards from the center of the explosion area.

After an air burst at a high altitude on a clear day there would probably be no significant residual radiation hazards on the ground, because most of the fission products, and unfissioned bomb material, would be carried to a great altitude by the hot gases resulting from the atomic explosion. They would then be widely dispersed and carried away by the winds at varying levels of altitude with ever increasing dilution. Contamination of air masses, particularly closely downwind of the explosion, might provide some degree of hazard to planes operating therein. Such a condition would probably be transient and might be injurious, depending on a variety of influencing factors. Should radioactive materials from such contaminated air masses "fall out" on the surface of the ground at sites far removed from the area of the explosion, they would probably create no significant health hazards, although they might be measurable in so-called tracer amounts. Such a situation might give rise to difficult problems in human relations but would probably not be hazardous to health.

Radiological Hazards Produced by Surface and Sub-Surface Bursts: In planning for radiological defense, one cannot entirely disregard the possibility of surface and subsurface bomb detonations.

In a surface burst, the radiological hazards produced at the actual time of detonation would be grossly comparable to those of an air burst, although the range of the radiant heat, flash and blast effects would be noticeably lessened. Persistent radioactive contamination of the ground would be encountered in the immediate target area and for variable distances immediately downwind of the explosion area. It might present a significant radiological hazard, particularly to personnel whose civil defense duties may require entry therein. Contamination of air masses would be much the same as that resulting from an air burst. In addition, there might be some contamination of nearby land surfaces as a result of heavy "fall out" and as a result of spread of ground contamination through surface drainage and movement of subsurface waters. Any distant downwind contamination attributable to cloud "fall out" would probably not constitute a significant health hazard of any kind, and it is unlikely that it could ever be the source of radioactive poisoning from the inhalation or ingestion of contaminated materials.

Should the bomb be detonated beneath the surface of a body of water, under the same conditions as in the second Bikini test, the radiological effects would probably differ widely from those produced by surface or high altitude explosions. Under these circumstances, the radiations released at the instant of detonation may largely be absorbed by the water and so be rendered of minor importance. On the other hand, contamination of air masses, though relatively limited in extent, may be of considerable severity. Nearby land areas and above-surface objects in the path of the "base-surge" and the "radioactive rain" which would accompany it, as well as the body of water itself, would doubtless be heavily contaminated with radioactive fission products. This contamination would persist for variable periods of time, depending on the rate of radioactive decay, dispersion and dilution and other factors. The significance of such a residual contamination could be determined only after analysis of the situation by qualified radiological defense personnel employing techniques now well established in practice.

"Fall Out": When the radioactive, metallic oxide particles in the bomb cloud collide with the particles of dirt, which are in general considerably larger, they adhere and the dirt particles in the cloud become contaminated with the radioactive substances. Then, when the violence of the disturbance due to the explosion has subsided, the contaminated dirt particles gradually fall back to earth, giving rise to the phenomenon known as "fall out." If the height of the bomb burst exceeds a certain value, there will probably be no detectable "fall out" since no extraneous particles will be sucked into the cloud. However, should the bomb be detonated relatively close to the ground, or on the surface of the ground, and considerable amounts of dirt and other debris were sucked into the radioactive cloud, the "fall out" would have to be considered as a danger until proved otherwise. Much the same situation would exist if the bomb were detonated at a low level above the surface of water, although then the "fall out" would consist mainly of water drops. In an underwater burst, detectable, but probably not dangerous, "fall out" might occur at a considerable distance from the site of the explosion. In an underwater burst, the really significant "fall out" would be that closely associate with the "base surge" and "radioactive rain" created by such an explosion, and this would be observed for variable distances immediately downwind of the explosion.

"Base Surge" and "Radioactive Rain": In the underwater test at Bikini a "base surge" and a "radioactive rain" were observed for the first time. Together they were responsible for the surface contamination that was observed within a radius of a few thousand yards downwind of the explosion. For a technical discussion of these two important and somewhat complicated phenomena, "The Effects of Atomic Weapons"[7] should be consulted.

Significance of Problems of Food Contamination in Civil Defense.—Foodstuffs from storage places, markets, restaurants or food-processing plants within the areas of residual contamination should be suspected of being contaminated and should be monitored before being used. Nonperishable foods found to be contaminated should not be destroyed until monitored by special radiological defense teams and they advise disposal.

After an atomic explosion, within the areas of residual contamination, foods in undamaged refrigerators, cans, bottles, jars and sealed packages may be used without monitoring, provided care is exercised in washing off any dust or liquid from the outside of the container or package before opening and precautions taken to prevent contaminated materials from getting into the food during the process of opening the container or removing its contents.

Under most unusual conditions certain risks might be encountered in the long-continued and repeated ingestion of animal or plant forms that take up radioactive elements from the environment and concentrate them within their own bodies. The control of such a problem would, however, not be difficult, and the medical specialists in radiological defense would be alert to the detection and evaluation of such an unusual situation.

Significance of Problems of Water Contamination in Civil Defense.—Contamination of water would not be a problem after an aerial burst such as at Hiroshima and Nagasaki.

The Bikini underwater test provided the ideal situation for maximum water contamination—it was a particular type of underwater burst, occurring in a deep body of salt water which is stagnant in nature and in which the exchange of water in and out is actually very small. Under these conditions, the radioactive contamination within the water tended to remain confined to the water, the bottom and the biological forms within that body of water. There was a considerable natural shifting of radioactively contaminated materials within this lagoon, and a potential hazard may have persisted with respect to food forms taken from it.

The hazard that might be created in rivers, lakes and harbors would vary, depending on the depth of the water at the site of detonation and the size of the body of water, the rapidity of exchange as a consequence of current, tide or otherwise and, of course, the magnitude of the original contamination. These are some of the technical matters to be considered in relation to a potential hazard of this nature. They would be of primary concern to "specialists teams" of the radiological defense organization, rather than to "area survey" monitors.

It now appears that the civil defense problems associated with exposures to internal radiation hazards of this nature and which are of relatively short duration (hours, days) are probably not as formidable as was once feared. The more complicated and possibly more serious problems would center around long-continued or repeated exposures through the drinking of contaminated waters or the eating of food forms derived directly, or indirectly, from waters so contaminated.

Modern municipal filtration systems, in those cities where these facilities exist, would provide a great deal of protection through their ability to remove such contamination. It would be possible to keep a close check on this matter at the filtration plants, and when required the contaminated materials of the filtration system could be replaced. The problem is one not too difficult to deal with technically, even in the most extreme conditions visualized. This problem would be of primary concern to specially trained public health radiological defense teams, rather than to area survey monitors.

The process of distillation, as employed in the nontarget ships at Bikini after the underwater test, effectively removed the radioactive materials by holding them in the evaporator. This provides substantial evidence as to the efficacy of this procedure in decontaminating water under the extreme conditions of contamination that characterized that test.

In this connection, it must be pointed out that radioactivity in measurable amounts does not necessarily mean radioactivity in injurious amounts. In the use of radioisotopes in medical diagnosis small amounts of radioactive materials, much too small to produce any injury, are employed in so-called tracer amounts. Radioactive contamination of water from anything but a Bikini type underwater burst would probably be of much the same significance. While it would be detectable, measurable and of technical interest, it is not likely to be of practical significance from the standpoint of causing injury to personnel except possibly as a result of prolonged and repeated ingestion of contaminated water or food products derived therefrom.

---

[7] The Effects of Atomic Weapons, Atomic Energy Commission and Department of Defense, Government Printing Office, Dec. 1950.

The techniques of study of such water would be much the same as those now in use in biological and medical laboratories where water is tested, and in those medical laboratories where the blood and urine of patients treated with radioisotopes is measured and studied. Similar techniques could be employed effectively to protect personnel from this form of hazard were it ever encountered. This would be done by special public health teams or "specialists teams' of the radiological defense organization, rather than by "area survey" monitors.

Water containing one-millionth of a curie of fission products per liter is considered safe for drinking. Many popular mineral waters contain more than this.

Some cities, such as New York, obtain their water supplies from sources removed from the city proper. In such circumstances the problems of providing safe water for drinking and household purposes would probably not be difficult or serious. Many cities do not have filtration facilities, so that the problems may require special consideration.

Decontamination Measures.—As used in radiological defense, decontamination means the removal of radioactive materials from the person or object contaminated with such materials. It does not consist of changing the rate of decay of the radioactive elements present. By moving the radioactive materials from one place to another, either partially or completely, one may serve a useful purpose or may simply shift the site of hazard from one place to another. The dispersion of radioactive materials in air or water, and on land surfaces, may reduce the amount of contamination at a particular site. It may, however, give rise to new problems at other sites. Generally, such dispersion, and the accompanying dilution tends to favor the protection of personnel. This is the active factor, which in association with "radioactive decay," constitutes nature's way of decontamination. There are a few important exceptions to this generalization. Under certain conditions, biological forms may tend to concentrate radioactive substances and a rather subtle and perhaps significant radiological hazard may develop where it is not expected.

Decontamination procedures as they apply to extensive land surfaces and buildings, and perhaps to a lesser extent to some large items of equipment, have not proved to be entirely satisfactory. On the other hand, it is possible to remove contamination from the external surfaces of the human body through the removal of contaminated clothing combined with a thorough washing and rewashing of the face, hands and body with soap and water. This is both practical and effective. It should be a routine procedure for personnel required to work in contaminated areas.

Small objects the surface of which are nonporous or nonabsorbent, may often be decontaminated by somewhat similar techniques. In certain circumstances, weak acids or other chemicals may be employed to advantage. Generally such materials as are absorbent are not readily, if at all, decontaminated. Wood, concrete, asphalt, soil and certain organic materials can rarely be decontaminated successfully.

Clothing will tend to prevent radioactive materials from coming into contact with the skin. In this sense only, may clothing be considered as being protective. When the contaminated clothing is removed, one phase of personal decontamination is carried out. When the contaminated clothing is being worn, and the radioactive material is not in direct contact with the skin, the beta particles or alpha particles emitted will usually not injure the skin although the gamma radiations emitted will penetrate the clothing and may produce injury.

The Armed Services Chemical Warfare Masks will prevent inhalation of radioactively contaminated materials and, when required, can be employed for this purpose by personnel who are working in contaminated areas and by those engaged in certain decontamination operations.

Exposure Tables.—In the atomic energy program, a standard has been set, called the "permissible dose" or "tolerance dose." This stipulates an exposure to the entire body that a man could experience every day in his life without danger of injury. This has been set at a maximum of 0.1 r a day with a weekly maximum of 0.3 r.

This applies to daily exposures. It is a very different matter when applied to a one-time exposure in emergency and to that accumulated in a period of a day or so. Under these conditions a person may be subjected to many times the daily "permissible dose" without injury.

In emergency civil defense operations and with exposures incurred within a few days the following points would obtain:

1. A person could probably be exposed to 25 to 50 r of total body radiation without incurring injury and be able to continue at his duties. If possible, he should not be exposed to any more radiation, at least not for several weeks. The Atomic Energy Commission has recommended to the Federal Civil Defense Administration that workers not be exposed to more than 25 r, and this recommendation should be followed.

2. A person exposed to 50 to 100 r of total body radiation might have some nausea and some changes in the number of cells in his blood, but he would most likely be able to continue his duties. Such exposures should most certainly be avoided if possible, and the individual should not be exposed to any more radiation, at least for many weeks.

3. A person exposed to 100 to 200 r might be incapacitated after the injury suffered began to take effect—probably some hours after exposure. He should not be exposed to any more radiation. It would be difficult to acquire exposures of this magnitude after the first day as a consequence of residual radiation hazards.

4. Exposures in excess of 200 r would in most instances produce "noneffectives," as injury and some degree of disability are practically certain.[8]

The interpretation of the medical significance of various levels of exposure to radioactive contamination is a function of the medical services rather than of the technical personnel of radiological defense. In the absence of medical personnel, monitors and technical personnel of the radiological defense organization would interpret their findings in accordance with the standards just described.

Exposure standards for other than penetrating gamma radiations lie beyond the technical scope of the present discussion.

It should be pointed out at this time that it is not the function of radiological defense monitors to determine, for purposes of medical diagnosis or treatment, the amount of exposure to radiation that individual casualties might have received during the period of initial radiation. Should it be deemed advisable to estimate the amount of radiation that might have been received by persons who were exposed in the open within certain ranges of the center of physical destruction, this should be done by technical and medical specialists on the staff of the civil defense headquarters, and not by monitors.

Types of Instruments Required for Technical Procedures.—The principal types of radiological defense equipment required for local operations are as follows:

Survey Meters: These instruments (Geiger counters and ionization chambers) are used to detect and to measure ionizing radiations, principally gamma radiation. Usually they measure the amount of radiation per unit of time, in which case they may be referred to as "rate meters." The requirements for these instruments will vary from a relatively large number of high intensity gamma ray monitoring instruments and a lesser number of low intensity gamma survey meters to a relatively small number of instruments that can detect alpha and beta particles at low intensities or in small amounts. The high intensity gamma survey meters should cover a range from 0.025 to 500 r per hour. The low intensity gamma survey meters are suitable for training purposes also. Specifications for civil defense monitoring instruments have been issued by the Federal Civil Defense

---

[8] For additional information on this problem see The Effects of Atomic Weapons,[7] table 11.28, page 342; figure 8.16, page 253; figure 8.17, page 254, and table 8.10, page 251. Also, Health Services and Special Weapons Defense, Federal Civil Defense Administration, Government Printing Office, Dec. 1950, p. 12.

Administration for the guidance of users and manufacturers.[9]

Dosimeters or Cumulative Dosage Indicators: These instruments (primarily special purpose electroscopes) are used to measure the total amount of exposure that has taken place over a particular period of time. They are worn by monitoring personnel to measure the total amount of radiation to which they have been exposed. With some dosimeters, the amount of the exposure may be read directly in the dosimeter. With others, the exposure is read indirectly by the use of a second instrument. The direct reading type is probably the most desirable for most civil defense purposes. Recently some simplified dosimeters have been developed that depend on the effects of ionizing radiations on a chemical indicator, or a special film preparation.

Other Laboratory Type Equipment: Other types of special equipment, of a laboratory nature, might be required for particular purposes. These will include counter scaler instruments with special alpha detectors, low intensity beta-gamma survey meters, portable alpha proportional counters, air filters, and sample preparation equipment and other instruments and accessories. It is not fitting at this time to more than mention that such equipment is available and could be readily procured if the need for such were known to exist. Such instruments are not needed in great quantities, or in such urgent haste, that they could not be readily provided from existing sources of supply and storage. Many items of equipment presently in use in radioisotope laboratories are well suited to this purpose.

Photographic Dosimetry: Photographic film badges may be worn by a person to measure the amount of external body radiation to which he is exposed. When the film is developed and compared with proper standards, the exposures can be measured. It is likely for both technical and operational reasons, that the use of such devices will be less suited to civil defense needs than in somewhat comparable situations in industrial plants and laboratories in which there are penetrating ionizing radiation hazards.

The issue, collection, development and measurement of film badges under conditions of civil defense requirements would take up too much time and effort to be practicable. Record keeping and the need for notification of involved personnel would be further hampering. While the use of such film badges would not be generally applicable to civil defense workers, under certain conditions associated with the persistence of a significant residual radiological hazard their use, on a limited scale, may be highly desirable and also practicable.

ORGANIZATION

Personnel.—The radiological defense organization will be manned by part time volunteer workers who will not receive pay for their services. They will be trained in the technical and operational aspects of their duties as part of the civil defense training program. They will not have had medical training and will frequently need advice from those who have had, because their function is primarily one of health protection and there are many medical implications associated therewith.

Monitoring Teams.—The backbone of the working organization will be the monitoring team. The composition of a typical monitoring team as suggested by the Federal Civil Defense Administration would be one "leading monitor" and two monitors equipped and qualified to discharge the duties assigned to them. They would be aided by three "assistants" who have not had special technical training but who have been trained to assist the monitors. To provide flexibility in assignment and discharge of duties, all monitors should be trained to serve either in "area survey operations" or in "service monitoring."

Area Survey Teams.—When assigned to the radiological monitoring of areas suspected of being contaminated, the monitoring teams will serve as "area survey teams."

Service Monitoring Teams.—When assigned to the monitoring of civil defense personnel working in potentially radiologically hazardous areas they will serve as "service monitoring teams."

Specialists Teams.—To solve some of the technically more difficult tasks, such as those involving radiochemical analyses, and to meet some of the other problems which require the services of trained and experienced specialists, a limited number of "specialists teams" may be required.

Headquarters Group.—A limited number of personnel will be needed to man the plotting rooms in civil defense headquarters and to assist in the direction of the activities of the monitoring teams. In addition, some personnel will be required to assist in the supply and maintenance of monitoring instruments.

Operations.—To function as a smooth-working civil defense service, there must be a proper organization and a suitable operation plan, both well integrated into the civil defense scheme of the community. The activities of the monitoring teams must be directed and they must be carried out according to a prearranged plan insofar as this is possible. Otherwise, there will be added confusion, and the mission of the health services of civil defense will not be attained. In the planning of the radiological defense operations leadership, patience and good common sense will be required. Where those in charge of radiological defense understand the missions and tasks of those persons in the other civil defense services, and when they in turn understand the mission of the radiological defense personnel, an effective cooperative scheme of operations can be effected. It cannot be done otherwise.

TRAINING

Radiological Defense (Monitors).—The Federal Civil Defense Administration has encouraged the establishment of courses for radiological monitors within the states. Such courses emphasize the practical aspects of the detection and measurement of radiation. They also stress the use of these techniques in civil defense operations. By limitation of the scope of the technical tasks to which monitors may be assigned, it has been possible to train personnel with a good general background of education to the level of proficiency that would be required in the discharge of "area survey" and "service monitoring" duties. Approximately one year ago, the Atomic Energy Commission provided leadership and assisted in the setting up of such training in many of the states. Leaders, trained in these courses, are now assisting in the conduct of similar courses of basic instruction within their states.

Medical Aspects of Radiological Defense.—The training of selected physicians, especially radiologists, in the medical aspects of radiological defense and in the medical problems associated with the possibility of a residual radiation hazard will be developed more actively in the future. These persons would then, as representatives of the medical services, act in the capacity of medical advisers in relation to the radiological defense services. There are a variety of problems requiring special attention at the hands of medical personnel who possess special knowledge in this new field of medical responsibility. The Atomic Energy Commission assisted in the conduct of some such courses this past year, and the instruction was of an intensive nature and at the postgraduate level.

Medical Aspects of Atomic Warfare.—It is generally recognized that all physicians and nurses should have some orientation instruction in the medical aspects of atomic warfare. The purpose of this instruction is to acquaint them with the medical and health problems that are peculiar to atomic attack, rather than to enable them to serve as medical or health advisers with respect to the more complicated technical aspects of radiological defense. An orientation course of this character can be satisfactorily conducted even when limited to only eight to 12 hours of actual instruction. Already, a great many classes of this character have been held, the instruction usually being given by persons who had attended courses given by the Atomic Energy Commission or the armed services. The purpose in describing this phase of instruction at this time is to point out its relation to the two courses that have just been described. It is important that the specific training objectives for a particular course of instruction be kept in mind when considering the planning of programs of instruction. Whereas as many physicians as possible should receive the orientation course in the medical aspects of atomic warfare, relatively few would need to attend the longer course in the medical aspects of radiological defense.

The Council on National Emergency Medical Services will cooperate closely with the Federal Civil Defense Administration in appropriate fields of medical training. State medical associations may be called on to participate actively in the planning and conduct of such instruction within their respective states.

---

[9] Civil Defense Radiological Monitoring Instruments Specifications, Federal Civil Defense Administration, Dec. 6, 1950. Available in state civil defense offices.

CONCLUSION

It has been my purpose to present an over-all picture of a new problem that is closely related to the responsibilities of the medical profession of this country. The need for a radiological safety scheme within civil defense is described, and many of the technical considerations involved are presented. The problems of organization and training are discussed only in order that attention may be directed to certain basic concepts of concern to the medical profession.

The medical profession has a special responsibility in matters of health protection even in civil defense. As physicians, we have a civil responsibility to know something about the problems associated with the possibility of residual radioactive contamination created by an enemy attack on civilian communities. In relation to these matters, we will be called on over and over again to give advice. As a profession, we have a particular appreciation of not only the medical but also the psychological problems involved. We can help to interpret them to our fellow men. It is in the national interest that we be as well prepared and as well informed as possible in order that we can fulfil our obligations in this respect in the best possible manner.

COUNCIL ON PHARMACY AND CHEMISTRY

The Council has authorized publication of the following report from the Committee on Research, a Standing Committee of the Council on Pharmacy and Chemistry.

R. T. Stormont, M.D., *Secretary.*

Previous publications[1] *by the Subcommittee on Steroids and Cancer of the Committee on Research have discussed the background of the problem of estrogen and androgen treatment of mammary cancer, outlined the procedures used in the current cooperative study sponsored by the Committee, and presented certain preliminary data obtained in this investigation. Details of some of the cases studied by participating investigators have also been published.*[2] *This report, prepared during the incumbency of Walton Van Winkle, Jr., as secretary of the Committee on Research, presents the Subcommittee's recommendations on the selection and treatment of patients with advanced mammary cancer and part of the data on which these recommendations are based. Ira T. Nathanson, Chairman; Frank E. Adair; Willard M. Allen; Earl T. Engle; Charles Huggins.*

Paul L. Wermer, M.D., *Secretary.*

CURRENT STATUS OF HORMONE THERAPY OF ADVANCED MAMMARY CANCER

MATERIAL STUDIED

Although records on more than 1,200 cases of mammary cancer treated with steroid hormones have been submitted to the Committee, only 886 cases have been included in the tabulations presented in this report. These cases were selected on the basis of the following criteria:

1. The diagnosis of mammary carcinoma was established by microscopic examination of tissue obtained at biopsy or operation or on the basis of other criteria such as roentgen evidence of pulmonary or osseous metastases.
2. The patient had very advanced primary, recurrent or metastatic disease not suitable for therapy by surgery or irradiation.
3. The patient had not been irradiated or castrated within the six-month period immediately preceding hormone therapy.
4. Roentgen ray therapy was not administered during hormone therapy, the patient was not castrated during therapy, nor was more than one hormone given during the period of observation.
5. The patient received treatment for at least four weeks.
6. Hormones were administered in accordance with the protocols established by the Committee.
7. All pertinent data on each case was recorded on the forms provided by the Committee.

The following is a tabulation of the number of patients receiving each of the hormones studied.[3]

	No. of Patients
Testosterone propionate (four schedules)	441
Methyltestosterone (200 mg. daily by mouth)	17
Diethylstilbestrol (15 mg. daily)	231
Ethinyl estradiol (3 mg. daily)	53
Premarin ® (30 mg. daily)	35
Estradiol diproprionate (5 mg. twice weekly)	21
Dienestrol (15 mg. daily)	24
Dimethyl ether of diethylstilbestrol (30 mg. daily)	35
Progesterone	11

A number of patients received the following compounds but the data are yet too limited for evaluation:

Methylandrostenediol
Testosterone cyclo pentenyl propionate
Monomestrol
Tri-para-anisyl-chloroethylene

Some patients received more than one hormone, although not simultaneously. In such instances, each period of hormone administration is regarded as a separate case. The data in table 1 justify this procedure, as far as this analysis is concerned. Whether previous hormone therapy may effect the patient's subsequent response in manner is not revealed in the present study.

The differences observed between the responses of patients who had received treatment and those previously treated with one of the hormones are within the statistical limits of error and hence are not to be regarded as significant for the number of cases observed.

SELECTION OF CASES

It must be emphasized that hormone therapy of mammary cancer is palliative only and not curative. Therefore, early diagnosis and removal by surgery remain the primary modes of attack on mammary cancer. In the presence of distant metastases, two forms of palliation are available: roentgen therapy and hormone therapy. A comparison of these forms of therapy has recently been made by Garland and his co-workers.[4] On the basis of these and other data, the Committee recommends that in the presence of localized and accessible osseous or soft tissue metastases surgery be performed whenever possible or adequate roentgen therapy be administered in lieu of hormone therapy. In the presence of widespread osseous or soft-tissue metastases, or lung metastases, hormone therapy *is often preferable as the primary therapeutic weapon.*

T.: Hormone Therapy in Cancer of the Breast, Soskin, S.: Prog. Clinical Endocrinology, New York, Grune & Stratton, 1950, p. 567.

Physiologic Age of Patient: Early investigators observed that the menopausal status of the patient apparently affected the results of hormone therapy, particularly the response to estrogens. The data obtained by the participating investigators in the Committee-sponsored investigation is shown in chart 1. These data indicated that the presence or absence of functioning ovaries probably has little significant effect on the response to testosterone propionate. However, it is apparent that postmenopausal women respond far better to the estrogens than do premenopausal women. Further analysis of the data reveals that the greater the number of years past the menopause the more likely is a satisfactory response to estrogen therapy. This is well illustrated in Chart 2 where the per cent of patients showing regression of soft tissue lesions is plotted according to the age of the patient. In general, the best results from estrogen therapy are obtained in patients more than five years postmenopausal.[5]

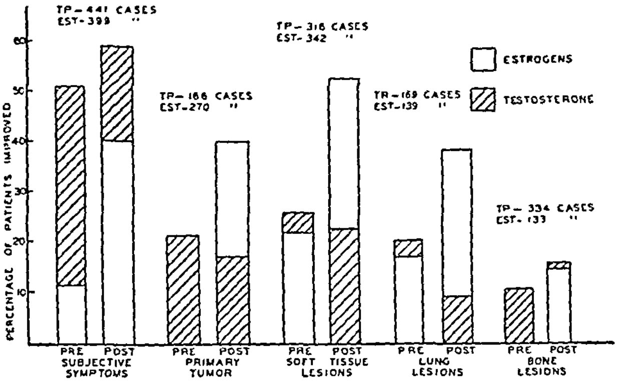

Chart 1.—Relation of menopausal status to response to hormones.

To further emphasize the importance of withholding estrogens from premenopausal patients with mammary cancer it should be mentioned that all of the patients who showed acceleration of their disease following estrogen therapy were in the premenopausal group or were in the menopause.

Choice of Hormone: It is obvious from Chart 1 that the hormone of choice for the premenopausal patient is testosterone propionate. In the postmenopausal patient with soft tissue lesions, estrogens appear to be far superior in producing an objective response than testosterone propionate. Where bone lesions predominate, there is little difference between response to estrogens and to testosterone propionate. However, since bone lesions are frequently the source of severe pain, and since testosterone appears to be superior to the estrogens in relieving subjective symptoms of the disease, most investigators prefer to use testosterone propionate in the treatment of osseous metastases.

Table 2 compares the values of the six most studied estrogens in the treatment of metastatic mammary cancer. According to these data ethinyl estradiol is slightly superior to the other estrogens. This superiority may be more apparent than real; however, since larger doses of other estrogens may be more efficacious than those used in this investigation, the difference in response might then disappear.

Unfortunately, the number of patients treated with methyltestosterone or methylandrostenediol has not been sufficient to permit valid comparisons with patients treated with testosterone propionate. In general, however, the dose of methyltestosterone employed has produced responses identical with responses to testosterone propionate. Methylandrostenediol, on the other hand, has not produced any satisfactory responses in the four patients in whom it has been used, with one possible exception.

The available data concerning progesterone are likewise fragmentary. Only one patient of the eleven treated showed any subjective improvement and one showed evidence of regression of soft tissue and bone lesions following progesterone therapy. One patient showed acceleration of soft tissue disease while receiving progesterone.

Location of Lesion: The distribution of metastases according to site and the response of these metastases to hormone therapy is shown in table 3. It is apparent, in the case of bone metastases, that the site of the lesion does not materially influence the response, although the data suggest that skull lesions may tend to respond more frequently than other bone metastases.

Among the soft tissue lesions, intra-abdominal metastases appear to respond least and, in estrogen-treated patients, skin and lymph node lesions respond most frequently. The apparent lack of response of abdominal lesions may be due to obvious difficulties in measuring or examining such lesions. In the testosterone-treated patients the response of skin and lymph-node lesions is not significantly greater than the response of other soft tissue lesions.

DOSAGE OF HORMONES

Testosterone Propionate: Four dosage schedules of testosterone propionate were explored. On all schedules, the weekly dose was given in three injections. Responses to the various dosage schedules are shown in Chart 3. The difference between the responses to the lowest dosage schedule (75 mg. weekly) and the highest (600 mg. weekly) is not significant. There is a suggestion that a dosage of 150 to 300 mg. weekly given in three divided doses may be optimal, but in this study 150 mg. weekly appeared to be as effective as 300 mg. weekly.

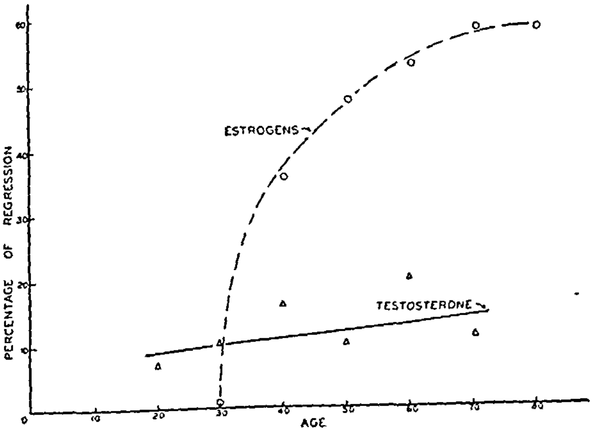

Chart 2.—Soft tissue lesion response.

It was not possible to determine the total dose at the time improvement began. Determination of the time of onset of improvement is subject to error, being dependent upon such factors as the frequency with which patients are seen by the physician and the frequency with which roentgenograms are taken. However, a crude measure of the relation of response to

3. The following pharmaceutical houses generously donated the hormones used by the investigators:

Abbott Laboratories: diethylstilbestrol, progesterone
Ciba Pharmaceutical Products: testosterone propionate, methyltestosterone ethinyl estradiol, estradiol dipropionate
Ayerst, McKenna & Harrison: Premarin, progesterone
Charles E. Frosst (Canada): testosterone propionate, dienestrol, diethylstilbestrol
Lakeside Laboratories: diethylstilbestrol
Wm. S. Merrell Co.: tri-para-anisyl-chloroethylene
Organon, Inc.: estradiol dipropionate, ethinyl estradiol, methylandrostenediol, methyltestosterone, testosterone propionate
Rare-Galen, Inc.: testosterone propionate, dienestrol
Schering Corp.: testosterone propionate, estradiol dipropionate, ethinyl estradiol, methyltestosterone
Schering Corp., Ltd. (Canada): ethinyl estradiol, testosterone propionate
E. R. Squibb & Sons: diethylstilbestrol, progesterone
Upjohn Co.: diethylstilbestrol, progesterone
Wallace & Tiernan Products: dimethyl ether of diethylstilbestrol, monomestrol
White Laboratories, Inc.: dienestrol
Winthrop-Stearns, Inc.: diethylstilbestrol

4. Garland, L. H., and others: Roentgen and Steroid Hormone Therapy in Mammary Cancer Metastatic to Bone, J. A. M. A. **144**: 997 (Nov. 18) 1950.

5. Nathanson, I. T., in Proceedings of Laurentian Hormone Conference, American Association for the Advancement of Science, Franconia, New Hampshire, Sept. 10-15, 1950, to be published.

total dose may be obtained from the data submitted to the Committee by comparing the incidence of favorable response to total dose in this large group of patients. Inspection of the data revealed that only 6 per cent of the patients who received less than 3 Gm. of testosterone propionate responded favorably, in contrast to about 20 per cent of those who received 3 Gm. or more. Subjective improvement was twice as frequent among patients who received 2 Gm. or more as among those who received less than 2 Gm.

It should be remembered, however, that the total dose is a function of the duration of treatment, and the data presented below suggest that duration of treatment is of greater importance than the total dose administered.

Estrogens: Dosage schedules of the various estrogens were not varied in this investigation. The doses used were ones known to produce an effect, but as yet there are no data indicating that these doses are optimal. The four estrogens given in daily doses of 15 to 30 mg. showed approximately the same degree of potency. Patients who received less than 2 Gm. total dose showed only 15 per cent subjective improvement, whereas those receiving 2 Gm. or more showed slightly more than 50 per cent subjective improvement. Objective improvement was twice as frequent in patients given 4 Gm. or more as in those given a total of less than 4 Gm. Again, duration of treatment is probably more important in determining the outcome of therapy than the total dose administered.

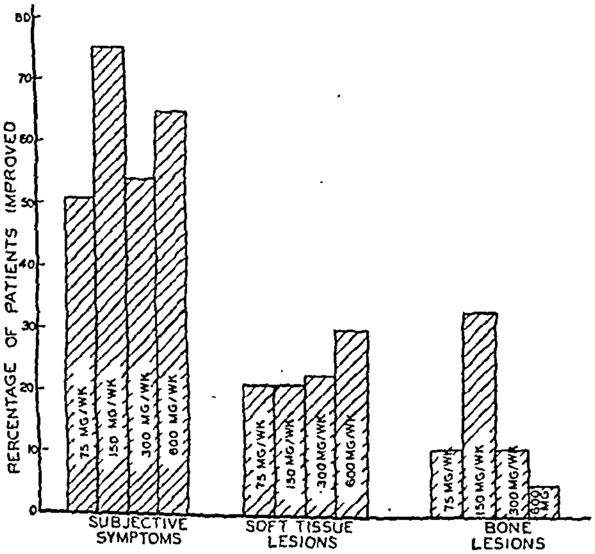

Chart 3.—Relation of dosage schedule of testosterone propionate to favorable response.

Ethinyl estradiol and estradiol dipropionate, because of their higher biological potency, were given in doses much smaller than those of the other estrogens. A total dosage of 200 mg. appeared to be minimal for a satisfactory response in about 75 per cent of the patients who exhibited objective improvement.

Methyltestosterone: Although only 17 patients were treated with methyltestosterone, the incidence of favorable response in patients receiving a total dose of 30 Gm. was between two and three times that in patients receiving less than 30 Gm. This figure is interesting because the weekly dose of methyltestosterone was five times the reference dose of testosterone propionate (300 mg. weekly) but the minimal total dose of methyltestosterone appears to be ten times that of testosterone propionate. The minimal duration of treatment with methyltestosterone is nearly twice that of testosterone propionate; thus, the difference in length of treatment corroborates the difference observed in minimal total doses.

DURATION OF TREATMENT

Testosterone Propionate: Although it was not possible to determine the exact time of onset of improvement in treated patients, the incidence of improvement was approximately twice as great in patients treated for more than three months than in those treated for a shorter time. This difference obtained under all dosage schedules, which suggests that although the total dose is important, the duration of therapy is equally or perhaps more important. A patient given 150 mg. weekly receives about 2 Gm. of testosterone propionate in a three month period and a patient given 300 mg. weekly receives about 4 Gm. in a three month period. These two dosage schedules were the ones showing the best responses.

TABLE 1.—*Relation of Prior Treatment to Subsequent Hormonal Response*

Prior Treatment	% of Subjective Improvement		% of Soft Tissue Regression		% of Bone Lesion Regression	
	Testosterone	Estrogen	Testosterone	Estrogen	Testosterone	Estrogen
None	59	39	24	53	13	18
Hormones	53	42	20	44	22	no cases

TABLE 2.—*Responses of Patients with Mammary Cancer to Six Estrogens*

Estrogen	Subjective Relief %	Primary Tumor Regression %	Soft Tissue Regression %	Lung Lesion Regression %	Bone Lesion Regression %
Diethylstilbestrol	39	42	53	29	14
Ethinyl estradiol	59	45	67	43	10
Premarin ®	35	45	44	8	16
Estradiol dipropionate	30	50	45	12	*
Dienestrol	46	13	42	17	*
Dimethyl ether DES	34	32	47	19	*

* Insufficient cases.

It should always be emphasized that these data only indicate a *minimum* treatment period and no effort has been made to determine the optimal or maximal duration of therapy. If a patient has not responded after three months and a total dose of 3 Gm., it is not likely that response will be obtained by further treatment.

TABLE 3.—*Response of Specific Metastatic Lesions to Testosterone Propionate and Estrogens*

Site of Metastasis	Testosterone		Estrogens	
	No. of Cases	Regressed, %	No. of Cases	Regressed, %

Lymph nodes	206	22	251	48

* Does not include pleural lesions, whereas in other tables pleural lesions are included under "lung" classification.

Estrogens: It is more difficult to determine the minimal duration of treatment for maximum response to the estrogens. Regression occurred only occasionally in bone and lung lesions of patients treated for less than six months. Soft tissue lesions in the majority of patients showed regressions after three months of therapy. The difference in time required for response of osseous and soft tissue lesions may be due to the necessity of depending on roentgen ray evidence of alterations in osseous and lung lesions, while visual and palpatory evidence is used in external lesions. This suggests that in patients with bone and lung metastases, therapy should be given for a prolonged period before it is considered ineffective.

Methyltestosterone: In the few cases studied bone lesions responded earlier than soft tissue or lung lesions: Of those patients with bone lesions who responded, over half have shown such response at the end of three months of therapy. However, no patient with soft tissue or lung lesions responded until five months of treatment had elapsed.

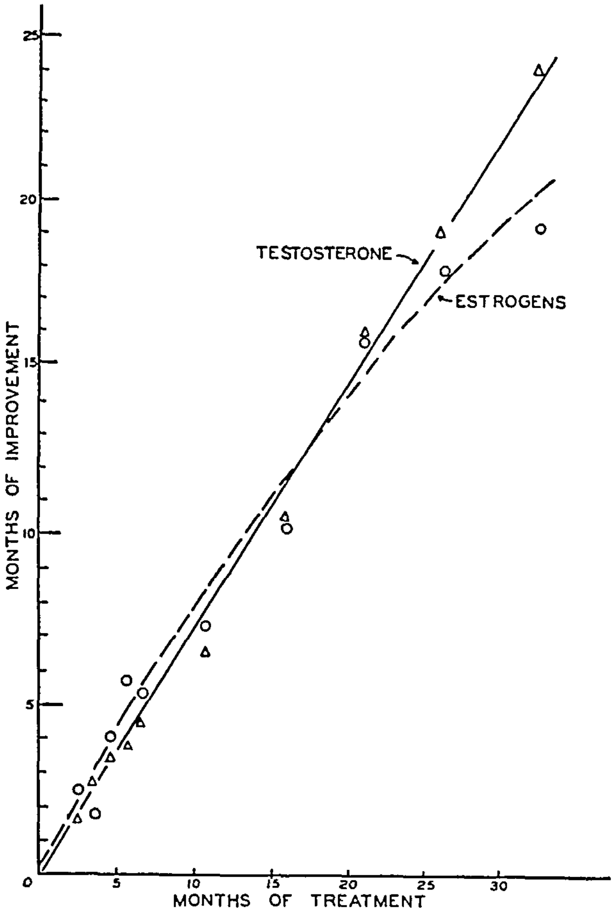

Chart 4.—Duration of subjective improvement.

DURATION OF IMPROVEMENT

Subjective Response: Although it is obvious that the duration of improvement should be related to the length of treatment, it is noteworthy that in the majority of cases the duration of improvement did not outlast the period of treatment. In many cases the disease became reactivated during treatment, necessitating cessation of therapy or change to another hormone. The duration of subjective improvement was similar in patients treated with testosterone propionate and those treated with estrogens except that a greater number of patients given testosterone experienced prolonged relief (18 months or more) (Chart 4).

Soft Tissue Regression: The duration of soft tissue regression was similar in patients treated with testosterone propionate and those treated with estrogens. There was an indication, however, (Chart 5) that the improvement lasted longer in patients treated with estrogens for five to 15 months than in those treated for similar periods with testosterone propionate.

Lung Lesion Regression: The duration of lung lesion regression with both testosterone propionate and estrogens was almost identical with that of soft tissue regression. Improvement continued slightly longer with estrogens than with testosterone propionate.

Bone Lesion Regression: In patients treated for 2 to 12 months, bone lesion regression is significantly longer with the use of testosterone propionate than with estrogens. In patients treated for more than 15 months, however, the duration of improvement is much greater with estrogens.

SURVIVAL

Garland et al.[4] have reported that palliative irradiation of patients with breast cancer metastatic to bone produced a mean survival time of 12 months. Most of the cases in the present series were even farther advanced than those reported by Garland: Approximately 85 per cent of the patients in this series had lesions too widespread to be amenable to irradiation or had previously received large doses of palliative roentgen irradiation. Nevertheless, the mean survival figures shown in table 4 closely approximate those reported by Garland for his series of patients treated with irradiation. These figures represent minimal survival times since they include only patients who have died at the time this report was prepared. Many patients still under treatment have survived for longer periods.

TABLE 4.—*Relation of Improvement to Survival of Patients with Advanced Mammary Cancer*

	Mean Time: Admission to Death			
	Testosterone		Estrogens	
Location of Lesions	Not Improved, Months	Improved, Months	Not Improved, Months	Improved, Months
Soft tissue..........	7.4	11.0	7.4	13.7
Bone lesions..........	8.9	13.6	8.9	14.4
Lung lesions..........	7.6	8.7	8.4	16.5
Mean	8.5		9.8	

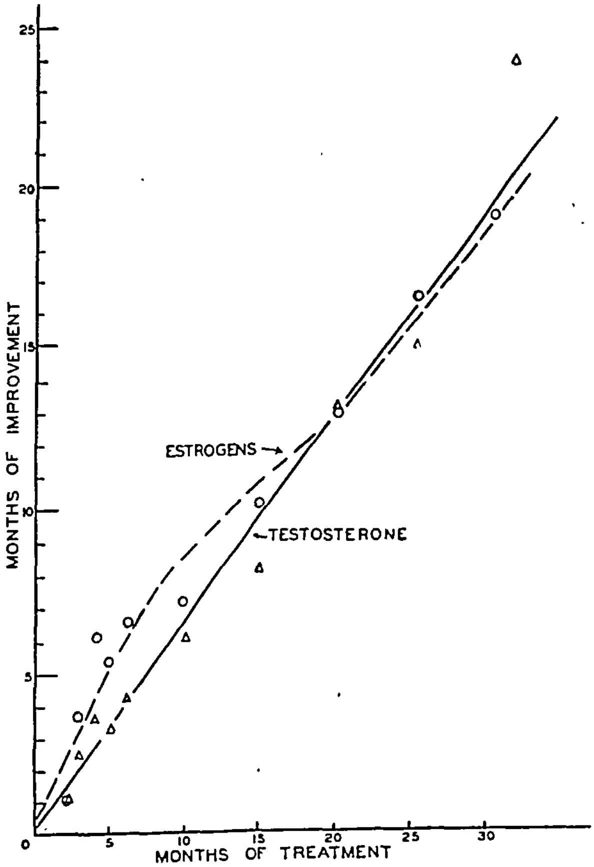

Chart 5.—Duration of soft tissue regression.

Patients aged 40 to 49 years who were treated with estrogens had a mean survival time of 7.6 months; patients aged 60 to 69 years, 9.1 months; those of 70 to 79 years, 10.6 months; and those of 80 to 89 years, 12.3 months (equal to the figure reported by Garland for patients with bone metastases). With testosterone propionate the mean survival times for patients aged 40 to 49 and aged 70 to 79 were 7.5 and 7.4 months, respectively. Thus, the older patients treated with estrogens lived longer than the younger ones, a paradox not seen in patients treated with testosterone propionate.

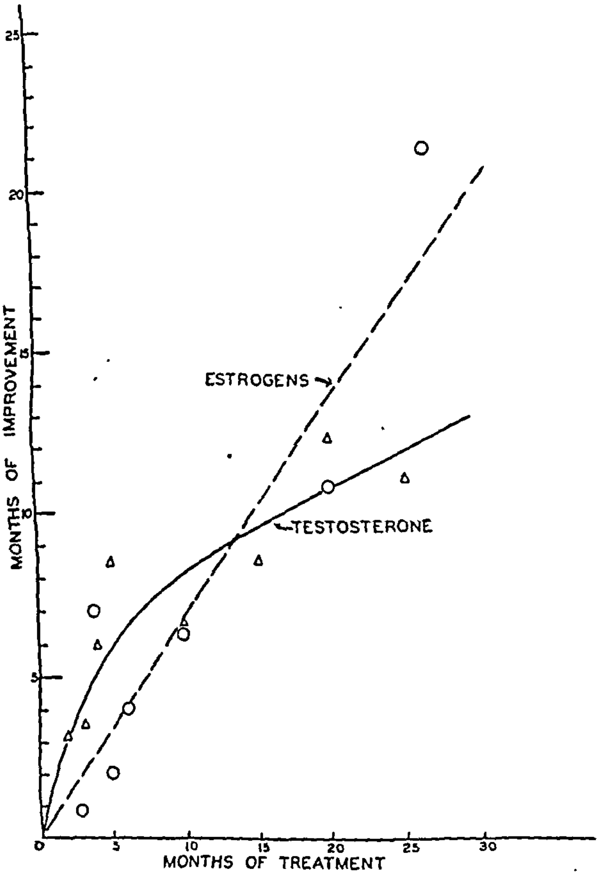

Chart 6.—Duration of bone regression.

Although it is possible that the nature and course of the disease in elderly people is different than that in younger ones, the disease being more lethal in the young, the difference in survival between the estrogen-treated and testosterone-treated patients in the older age group is significant.

That steroid therapy may prolong life is demonstrated by the comparison of survival times for improved and unimproved patients (Table 4). Patients whose condition was improved by treatment with estrogens lived nearly twice as long as those showing no improvement. Some of the differences shown in this table may be due to an automatic selection of cases. Patients showing no improvement may have been in poorer condition, had more advanced disease or may have been otherwise less satisfactory candidates for steroid therapy than those who showed improvement. This point will be subject to further study by the Committee. The fact that the survival times are measured from the admission to this study, and, further, that this point is somewhat variable with relation to the stage of the disease, introduces an uncontrolled variable into the estimate of survival times. Probably this is not too important a factor in a series as large as that under discussion.

SIDE EFFECTS

Testosterone Propionate: The large doses of testosterone employed frequently provoked unpleasant side effects, the commonest being those related to the masculinizing action of this hormone: hirsutism and deepening of the voice. An excellent discussion of these side effects has been given by Kennedy.[6] Table 5 lists the principal side effects noted and indicates that the incidence with which these effects are observed is approximately the same at all dosage levels. Not indicated in this chart is the observation that at the higher dosage levels these effects tend to be more pronounced. Furthermore, the longer the patient is treated, the more likely are these side effects to be observed.

Two side effects, edema and hypercalcemia, are potentially dangerous when present to a marked degree. Edema, observed in about one-fourth of the patients, results from salt retention. In elderly patients with lowered cardiac reserve or with preexisting cardiac impairment, this condition may precipitate cardiac failure. Such a complication has been observed in several patients in this series. At the earliest signs of edema, usually weight gain without concomitant increase in appetite or food intake, the patient should be placed on a salt-restricted diet and ammonium chloride administered. In the presence of frank edema, mercurial diuretics should be administered and the testosterone propionate should be discontinued, at least temporarily.

Spontaneous hypercalcemia is not uncommon in patients with osseous metastases, particularly if they are confined to bed. This will occur in about 10 per cent of patients.[7] However, testosterone propionate administration may also produce hypercalcemia in patients with osseous metastases. A high level of circulating ionized calcium can lead to kidney damage, central nervous system depression and may be fatal. The patient should be watched carefully during therapy and the blood calcium level determined at frequent intervals. Early signs indicating possible hypercalcemia are drowsiness, anorexia and nausea. Later signs are stupor and atonicity. Treatment by cessation of hormone therapy is usually sufficient to combat mild degrees of hypercalcemia; in the presence of severe degrees of this complication, Shorr has suggested intravenous infusion of 2.5 per cent sodium citrate in amounts sufficient to produce early, mild signs of tetany.[8] This therapy has been administered successfully to several patients in this series.

Methyltestosterone: The side effects of methyltestosterone are similar qualitatively and quantitatively to those of testosterone propionate. Liver damage has been reported in males receiving methyltestosterone.[9] One of the 17 patients administered methyltestosterone developed jaundice but no other evidence of impaired liver function after receiving 66 Gm. of the drug.

Estrogens: Table 6 lists the side effects observed with the various estrogens. Edema was fairly common during estrogen therapy. The mechanism is the same as for testosterone propionate and the same preventive measures should be employed.

Hypercalcemia, while less common than with testosterone, does occur and patients with osseous metastases should be observed carefully for this complication.

TABLE 5.—*Side Effects of Testosterone*

	75 Mg./Wk., %	150 Mg./Wk., %	300 Mg./Wk., %	600 Mg./Wk., %
Hirsutism	61	65	62	74
Incr. libido	36	27	24	19
Edema	25	29	28	23
Voice change	72	69	69	61
Bleeding	3	6	4	6
Acne	39	29	27	23
Flushing	33	22	17	16
Nausea	8	12	18	22
Vomiting	6	6	14	16
Loss of hair	6	10	4	3
Hypercalcemia	8	8	9	13

Nausea and vomiting were observed during therapy with every estrogen. This side effect frequently disappeared after two or three weeks of therapy, but occasionally was severe enough to require discontinuance of treatment. Frequently, another estrogen will be found not to give these side effects and may be substituted.

Acceleration of tumor growth has been observed following hormone therapy most frequently in women treated with estrogens in the premenopausal or menopausal years. A few instances of acceleration have been observed following testosterone and progesterone therapy. This development calls for immediate cessation of hormone therapy.

HISTOPATHOLOGY OF TREATED TUMORS

Serial biopsies of accessible lesions obtained in this study have been investigated by a group of consultants in Pathology, Dr. Lauren V. Ackerman, Dr. Fred Stewart and Dr. Arthur Purdy Stout. The Armed Forces Institute of Pathology made facilities available in the American Registry of Pathology for collection and study of pathologic material submitted by the collaborating investigators. Dr. Hugh Grady, Scientific Director of the American Registry of Pathology, and his associates screened all material submitted and selected material for review.

The objective was to determine, if possible, whether the clinical effects observed were brought about by an action on the tumor cell or the stroma, or by some other mechanism which could be identified morphologically. Many of the cases were incomplete and there were very few lung and bone specimens. In no instance did the pathologist have adequate material of lesions of the lung or bone which showed prominent regression; study of such specimens might be of value.

TABLE 6.—*Side Effects of Estrogens*

	Diethylstil., %	Ethinyl Estradiol, %	Premarin, %	Estrad. Diprop., %	Dienestrol, %	Dimethyl Ether DES, %	Progesterone, %

Pigmentation axilla	21	36	5	23	13	34	0
Hypercalcemia	3	2	5	0	0	3	0
Incontinence	10	15	11	5	4	6	0

Many of the tumors obtained from cases showing clinical improvement showed no detectable histological changes. When affected by the hormones, the gamut of degenerative and necrotic changes and the resulting fibrosis are indistingishable from comparable changes induced by irradiation. Fibrosis and production of elastic tissue which sometimes follows treatment are also comparable to similar senile changes in the skin. In some instances following steroid therapy, skin nodules were completely free of tumor and there were focal areas of absence of tumor within the breast itself. In a few instances, metastatic carcinoma within the regional axillary nodes showed complete disappearance. When the treatment produces a destructive effect on tumor tissue it does not act equally on all of the tumor but to varying degrees so that some of the tumor may be completely destroyed, some is damaged but may recover and some seems unaffected. This is best seen in mastectomies after treatment.[10] It is possible that further information concerning sequential changes in tumor prominently affected by steroids could be obtained by better timing of the biopsies of regressing cases of carcinoma of the breast in which there are numerous satellite skin nodules.

In the mastectomy specimens the mammary gland tissue seldom showed changes which could be ascribed to treatment; even with extensive degeneration necrosis and scarring of the tumor, mammary gland tissue is usually but not always unaffected. The effect on the cells might be due to vascular damage or to a direct action on the cells. Unfortunately, the limited number of cases reviewed precluded intensive study. The vascular effect does not seem to be a true infarction, since this should result in death of all tissues in a given area, which very rarely happens. A reduction in nutrition might result in the effects noted, but there is no positive evidence of this.

In almost all of the autopsy specimens the hormonal effect upon the carcinoma had ceased and the lesions were growing vigorously. Only one lung metastasis was seen which seemed to show some cell swelling and nuclear pyknosis suggesting a continued hormonal effect. None of the bone sections with tumor showed any recognizable effect on the tumor cells including a case in which the frontal bone was biopsied after very marked roentgen evidences of reossification. In this biopsy there was no histological evidence of new bone formation. If the endocrine organs in a group of autopsies were studied, further information of value might be obtained.

No definite opinion could be formed concerning the relationship of breast tumor types to hormone sensitivity nor the influence of the amount of fibrous stroma or its vascularity on the effect. There were too few cases showing any effect to make this possible. The impression was gained that neither histological type nor amount and nature of the stroma are guides to hormone sensitivity any more than they are guides to radiosensitivity.

The consultants in pathology concluded that ordinary histological techniques can throw no light on the mechanism by which the clinical effects are brought about. The development of new cytochemical techniques may open another approach to this problem.

CONCLUSIONS

1. The best curative measure for mammary carcinoma available at present is early diagnosis and radical surgical removal of the tumor and surrounding tissue.

2. Three palliative measures are available to deal with metastatic mammary cancer: surgery for localized lesions, irradiation and hormone therapy. For most osseous or soft tissue lesions, irradiation is the treatment of choice; lung lesions, and very widespread osseous or soft tissue metastases may best be treated with hormone therapy.

3. The response of lesions to testosterone propionate does not appear to depend particularly on the physiologic age of the patient, whereas, estrogen therapy is ineffective and dangerous in premenopausal patients or patients at the menopause. The effectiveness of estrogen therapy of soft tissue and lung metastases appears to increase with the age of the patient.

4. Testosterone propionate is the hormone of choice for treatment of premenopausal women regardless of site of lesions. However, it should be remembered that castration is usually more effective in the premenopausal woman, and this should be the treatment of choice if there are no contraindications. In women five years or more postmenopausal, estrogens are the hormones of choice for treatment of soft tissue and lung metastases. Although osseous lesions of postmenopausal women respond equally to testosterone propionate or to estrogens, the superiority of testosterone in controlling subjective symptoms, particularly pain, makes it appear to be the drug of choice for these metastases.

5. The location of bone metastases does not influence the response. Skin and lymph node lesions respond more frequently than do other soft tissue lesions. Abdominal metastases are reported to respond least often.

6. An effective dosage schedule of testosterone propionate appears to be 50 mg. given three times weekly. The minimum total dose is about 3 Gm. and the minimum length of therapy should be three months before concluding that a patient will not respond.

7. The minimum total dose of diethylstilbestrol, dienestrol, Premarin and the dimethyl ether of diethylstilbestrol appears to be about 4 Gm. and the minimum duration of therapy about three to six months. For ethinyl estradiol and estradiol dipropionate, the minimum total dose appears to be 200 mg. and the minimum duration of therapy from 3 to 6 months.

---

[10] These mastectomy specimens were generously furnished by Dr. I. T. Nathanson of Massachusetts General Hospital.

8. For the present, it is suggested that treatment with hormones should be continued until reactivation or steady progression of the disease occurs. Cessation of therapy after reactivation may result in another regression. Change of therapy to another hormone may also bring about a second favorable response.

9. The mean duration of improvement of soft tissue lesions, treated either with testosterone or estrogen is about 10 to 12 months; for bony lesions testosterone will produce a mean duration of improvement of about 11 to 12 months whereas the mean duration of improvement with estrogen is 16 to 18 months.

10. The mean survival time after admission to this study of all patients who have died is 8.5 months for testosterone-treated patients and 9.8 months for estrogen-treated patients. Patients who showed improvement survived about twice as long as those who did not show improvement.

11. Both testosterone propionate and the estrogens, in these doses, produce unpleasant side effects in a high proportion of patients. Two side effects, edema and hypercalcemia, are dangerous and require constant observation of the patient and early corrective measures. Estrogen therapy may cause severe uterine bleeding requiring curettage. With prolonged bleeding, the possibility of endometrial carcinoma or activation of fibroids must be considered.

12. Histologic examination of biopsy and autopsy material collected in this study has not revealed any changes in tumor cells or stroma which would suggest an explanation of the mechanism of hormonal action in metastatic breast cancer. At times, however, there was complete disappearance of tumor in satellite skin nodules, in focal areas within the breast carcinoma and in occasional lymph nodes previously replaced by tumor. The changes seen both in the tumor and stromal background in the cases responding to steroid therapy are comparable to the effects of irradiation.

COUNCIL ON FOODS AND NUTRITION

The following statements have been adopted by the Council on Foods and Nutrition for publication.

JAMES R. WILSON, M.D., *Secretary.*

WHOLESOME FOOD

The purpose of examining the concept of a wholesome food is to reemphasize the necessity for appraising all chemical technologic aids before they are used in connection with the growth, storage, preparation, or final processing of foods.

It long has been recognized that nutritional status is closely related to the quality of food eaten. It also has been recognized that wholesome foods must be clean and free from extraneous matter that may be incorporated as the result of careless or uncleanly methods of growth, storage or processing. Although micro-organisms which contribute to the value of a food may be incorporated intentionally or accidentally, disease-producing organisms have no place in foods intended for human consumption.

Although these basic concepts have acquired general recognition, the development recently of a large number of chemical technologic aids has emphasized the necessity for reexamining our idea of a wholesome food, particularly from the point of view of its freedom from chemical additives which may be harmful to the consumer because of toxicologic effects or because their incorporation in food causes or makes possible the reduction of nutritive value. For this reason the following short definition is offered:

A wholesome food is a product which makes a significant contribution to human dietary requirements and which is clean and free from micro-organisms and chemical additives of such quality or in such quantities that they may be directly injurious or result in reduced nutritional quality.

THE USE OF ALUMINUM COOKING UTENSILS IN THE PREPARATION OF FOODS

Periodically rumors are circulated to the effect that foods cooked in aluminum cooking utensils are deleterious to health because of injurious substances imparted by the vessel. Thus it becomes necessary to again call attention to pertinent facts about aluminum.

Aluminum abounds in the earth's crust and is widely distributed in nature being present in a wide range of edible plants. Undoubtedly man has ingested small quantities of aluminum daily since he came upon the earth. Aluminum compounds are also important and useful therapeutic agents.

The possibility that aluminum utensils can impart injurious agents to the foods cooked in them has been extensively investigated. Up to the present time there has been no cogent scientific evidence indicating that the minute traces of aluminum that may be imparted to food in the process of cooking are in any way injurious to the consumer. As for the rumor that the use of food prepared in aluminum cooking utensils is a factor in the causation of cancer, it may be added also that there is absolutely no scientific basis in support of this view.

In view of these facts it is the opinion of the Council that the use of aluminum cooking utensils is in no way injurious to health.

ACCEPTED FOODS

The following products have been accepted as conforming to the rules of the Council. JAMES R. WILSON, M.D., *Secretary.*

H. J. Heinz Company, Pittsburgh

HEINZ STRAINED SWEET POTATOES. Ingredients: Sweet potatoes, salt and water to prepare.

Analysis (submitted by manufacturer).—Total solids 14.56%, moisture 85.44%, ash 0.78%, fat (acid hydrolysis) 0.20%, protein (N × 6.25) 0.81%, crude fiber 0.61%, carbohydrates other than crude fiber (by difference) 12.16%, total sugar (as sucrose) 5.77%.

Vitamins and Minerals	Per 100 Gm.
Vitamin A activity	4360 I.U.
Thiamine	0.026 mg.
Riboflavin	0.024 mg.
Ascorbic acid	4.8 mg.
Nicotinic acid	0.230 mg.
Calcium	21.0 mg.
Phosphorus	30.0 mg.
Iron	0.25 mg.
Copper	0.12 mg.
Salt	400 mg.

Calories.—0.54 per gram; 15 per ounce.

Use.—For use in the feeding of infants, convalescents and others requiring a soft diet.

Reid Murdoch & Company, Division of Consolidated Grocers Corporation, Chicago.

MONARCH BRAND DIETETIC PACK GRAPEFRUIT SECTIONS consists of the fruit itself, packed in water without any added sugar or salt.

Analysis (submitted by manufacturer).—Available carbohydrates (total carbohydrate minus crude fiber) 7.0%, fat (ether extract) 0.7%, protein (N × 6.25) 0.6%, ash (minerals) 0.4%, sodium 8.6 mg./100 Gm., potassium 151 mg./100 Gm.

Calories.—0.35 per gram; 9.9 per ounce.

Use.—For use in calory-restricted, low sodium and other therapeutic diets.

MONARCH BRAND DIETETIC PACK BLACK RASPBERRIES consists of the fruit itself, packed in water without any added sugar or salt.

Analysis (submitted by manufacturer).—Available carbohydrates (total carbohydrate minus crude fiber) 9.0%, fat (ether extract) 1.0%, protein (N × 6.25) 1.1%, ash (minerals) 0.4%, sodium 0.44 mg./100 Gm., potassium 111 mg./100 Gm.

Calories.—0.50 per gram; 14.2 per ounce.

Use.—For use in calory-restricted, low sodium and other therapeutic diets.

MONARCH BRAND DIETETIC PACK SWEET GREEN PEAS consists of the vegetable itself, packed in water without any added salt.

Analysis (submitted by manufacturer).—Available carbohydrates (total carbohydrate minus crude fiber) 9.0%, fat (ether extract) 0.4%, protein (N × 6.25) 4.0%, ash (minerals) 0.3%, sodium 3.0 mg./100 Gm., potassium 78 mg./100 Gm.

Calories.—0.57 per gram; 16.2 per ounce.

Use.—For use in low sodium and other therapeutic diets.

1951 CLINICAL SESSION TO BE HELD IN LOS ANGELES

Because of conflicting meetings, the unavailability of the Coliseum, and other considerations, the 1951 Clinical Session will be held in Los Angeles instead of in Houston, as originally planned. The action was taken on the recommendation of the Local Medical Committee on Arrangements and the Texas State Medical Association. Los Angeles was selected by unanimous vote of the Board of Trustees. The dates will remain unchanged—December 4-7, inclusive. The scientific exhibits will be in the Shrine Convention Hall.

ACUTE PHOSPHORUS POISONING

The diagnosis, symptoms and treatment of acute yellow phosphorus poisoning are discussed in a recent article by Diaz-Rivera and co-workers.[1] The presentation is based on data gathered from 56 cases of poisoning. Opportunity for studying such a large series of cases was attributed by the authors to the frequent attempts at suicide with phosphorus-containing rodenticidal pastes among Puerto Ricans. It is known that as little as 15 mg. of yellow phosphorus may produce severe toxic effects, while the fatal dose is generally considered to be about 100 mg. In a series studied by Diaz-Rivera and his colleagues, the estimated amount of phosphorus ingested ranged from 0.19 to 6.30 Gm., the average being 1.13 Gm. In five patients who ingested an average of 2.5 Gm. the course of action of the poison was fulminating, the patients dying within 12 hours from peripheral vascular collapse. Nine patients who ingested an average of 1.28 Gm. survived 13 to 24 hours. In the majority of these patients, restlessness, delirium and periods of toxic psychosis were manifest before death. All were intensely thirsty and suffered from severe nausea and vomiting, the vomitus frequently being bloody. Hepatomegaly developed in a few, but none were jaundiced. Five patients who had ingested approximately 1.5 Gm. did not die until the second day of illness. In addition to restlessness, emesis and delirium, hepatomegaly developed in all these patients and some became jaundiced. In many there was azotemia and oliguria. Terminally, the blood pressure reached shock levels. Two patients who had ingested 1.57 Gm. survived two to three days. Jaundice and oliguria developed in both, and their urine contained albumin and hyaline casts. Myocardial damage, thought to be the cause of death, was demonstrated by electrocardiographic studies. Of the remaining 35 patients who had ingested comparatively moderate amounts, 29 recovered, the others surviving at least five days. In the milder cases, symptoms appeared within 48 hours and included nausea, anorexia, epigastric pains and disagreeable taste in the mouth. Vomiting and constipation were not unusual. In others, severer manifestations developed within four to five days and consisted of severe vomiting, jaundice, hemorrhagic tendencies due to hypoprothrombinemia, oliguria and azotemia. Terminal manifestations included restlessness and toxic psychosis. It was noted that in some cases hyperphosphatemia developed after the fourth day. It was suggested that the phosphorus was initially promptly fixed by the body tissues, especially bone, and that with changes in acid-balance it was discharged into the circulation. This might explain the late manifestations of severe toxicity observed in some of the patients. The authors feel that, in acute phosphorus poisoning, immediate deaths are caused by peripheral vascular collapse, due either to a direct or an indirect effect on the cardiovascular system. With longer periods of survival, renal damage becomes manifest, while late deaths may be due to the combination of hepatic, renal and cardiac failure.

Treatment was directed at removal of the poison from the stomach by gastric lavage with potassium permanganate, prevention of further absorption by purgation with castor oil and general supportive measures designed to protect the organs most severely affected when absorption has taken place. Such measures included intravenous dextrose; high protein, high carbohydrate, and low fat diet; vitamin B complex, and crude liver extract. Five patients were given methionine, most of which, however, was lost through vomiting. Twenty-four patients received dimercaprol with poor results. Blood transfusions were considered contraindicated because of the fear that they might overload an already deficient circulation. The authors conclude that the deaths due to peripheral vascular collapse or to acute heart failure were unavoidable. They feel, however, that renal changes are due to disturbances in renal blood flow caused by the low systemic blood pressure and are as a rule reversible. Hence treatment of acute yellow phosphorus poisoning should be directed toward restoring the systemic blood pressure among those suffering from shock and toward obtaining proper hydration.

ANTIBIOTICS AND GROWTH

One of the notable achievements of the past few years has been the development of a number of new antibiotics, which have considerably strengthened the physician's armamentarium for the control of various bacterial infections. It is interesting to learn, however, that the value of antibiotics may extend beyond their original significance as bacteriostatic agents. The newly discovered property of growth promotion in experimental animals may become as important to man as the antibiotic property for which these substances were originally developed.

The discovery that certain antibiotics act as growth stimulants in animals dates back several years, particularly to the incidental observation in 1946[1] that chicks given streptomycin grew at a somewhat faster rate than untreated controls. This unexpected result received little attention until, in 1949, another group of investigators,[2] studying the effects of the then recently isolated vitamin B_{12} on the growth of chicks, found that chicks given a crude concentrate of vitamin B_{12} grew at a more rapid rate than chicks given the pure, crystalline vitamin. At the time, the results were interpreted as suggesting that vitamin B_{12}, or at least the "animal protein factor," was multiple in nature. The crude concentrate of vitamin B_{12} in question was prepared from cultures of Streptomyces aureofaciens; subsequent chemical fractionation of this material, however, finally yielded a yellow crystalline compound, totally different from vitamin B_{12} but extremely active in promoting growth. The crystalline material showed the physical and chemical properties of aureomycin, one of the newer antibiotics. Subsequent studies with known pure crystalline aureomycin demonstrated that this substance was responsible for the observed growth stimulation.[3] In rapid succession a number of other investigators confirmed the growth-promoting effect of crystalline aureomycin in chicks and also in a number of other species, including pigs, rats, turkeys and cattle. Also, it was soon shown that several other antibiotics, including penicillin, streptomycin, chloramphenicol and terramycin, exert similar favorable effects on growth.

The mode of action of the various antibiotics in accelerating growth has not yet been established. One explanation would appear to be that they alter the intestinal flora, perhaps decreasing the number of bacteria having some possible deleterious effect on the growth of the host organism and increasing the micro-organisms that are favorable to the growth of the host. The latter micro-organisms are believed to function by way of the synthesis of certain vitamins or perhaps other substances beneficial in supplementary amounts to the growth of the host organism. However, investigations showing that parenterally administered or partially inactivated antibiotics still exhibit growth-promoting activity suggest that the antibiotics per se may be responsible for the observed acceleration of growth. This problem remains to be solved.

The widespread importance of the foregoing observations is at once apparent. Already commercial poultry and stock feeds enriched with various antibiotics or their concentrates are on the market. Poultry and stock growers are claiming a resulting average increase in growth of approximately 30 per cent over other animals fed the usual well balanced rations. The significance of this fact in terms of an increased supply of meat and poultry and, in turn, of probable lower prices and better protein nutrition for a larger portion of our population is obvious.

The implications of the foregoing work may extend even further than immediate practical applications. For example, a recent claim appeared in the literature[4] that aureomycin produced a definite hematologic response and improvement in five cases of Addisonian pernicious anemia. The beneficial effect of the antibiotic was attributed to its effect on the intestinal flora. While this study is obviously preliminary in nature and must be adequately confirmed before conclusions are warranted, it nevertheless points to another important potential usefulness of the antibiotic agents to man. Likewise, the observation again emphasizes the importance of normal gastrointestinal function to the health and well-being of the individual.

EXPERIMENTAL TELEVISION PRODUCTION PACKETS

The medical profession is examining the problem of educational employment of television, the latest medium for communicating with the public. The success of medical telecasts on closed circuits sponsored by commercial firms interested in medical progress has been well demonstrated. Telecasting of medical subjects to the public requires a considerably different approach.

Television is a costly medium because of expensive equipment, large personnel requirements and the need for a great deal of space, both for rehearsal and production. The number of available television channels is limited, and no channels have been assigned for educational broadcasting. Because of the high cost of the medium, stations are much more reluctant to offer free time for educational features than has been the case with radio, which is a much less costly medium.

In addition, the preparation of telecasts involves an appreciation of the fact that, while television has some of the aspects of the theater, some of the movies and some of radio, it is in fact not merely a combination of these but a new medium with new characteristics, new techniques and a new language. The Bureau of Health Education, under special authorization from the Board of Trustees, has prepared a television manual which is available without cost to county medical societies on request. This has been prepared by television experts under the supervision of the Bureau. In addition, the Bureau recently telecast a program, "Dr. Webb of Horseshoe Bend," which was kinescoped (a kinescope is a film reproduction of the original telecast with sound), and the kinescopes have since been shown in 45 of a possible 65 television communities and have been well received. This telecast was costly.

[1] Moore, P. R.; Evenson, A.; Luckey, T. D.; McCoy, E.; Elvehjem, C. A., and Hart, E. B.: J. Biol. Chem. **165**: 437, 1946.

[2] Stokstad, E. L. R.; Jukes, T. H.; Pierce, J.; Page, A. C., and Franklin, A. L.: J. Biol. Chem. **180**: 647, 1949.

[3] Stokstad, E. L. R., and Jukes, T. H.: Proc. Soc. Exper. Biol. & Med. **73**: 523, 1950.

[4] Lichtman, H.; Ginsburg, V., and Watson, J.: Proc. Soc. Exper. Biol. & Med. **74**: 884, 1950.

Another approach to the television problem is to make available to local societies the materials for conducting a local telecast. This has been done by the Bureau in the form of television production packets. Each packet consists of an adequate supply of scripts plus lists of "properties" which must be assembled plus the necessary titles and explanatory material either on charts or film strip. These packets are available to local medical societies without cost. There are 12, each dealing with one of the following subjects:

1. School Health Examination
2. Home Care of the Sick
3. Cause of Backaches
4. First Aid
5. Snake Venoms and Antivenins
6. Safeguarding Children's Eyesight
7. Child Care
8. Preventive Medicine
9. Blood Pressure
10. The Human Heart
11. Slowing Down in Middle Life
12. Cancer

There are only three ways in which television can be made available to the medical profession as a tool for health education: (1) the kinescope, prepared and distributed by the American Medical Association and placed locally by county societies; (2) the telecast package, as above described, which will require more local preparation, and (3) sponsored broadcasting on the networks. All these possibilities are being explored.

The Bureau urgently requests all local medical societies to consider carefully the possibility of engaging in telecasting. The Bureau also solicits frank comments as to the local evaluation of materials made available. Television is in itself a new medium. Successful employment depends on free interchange of information and suggestions.

A NEW NITROGEN MUSTARD CONGENER IN CANCER CHEMOTHERAPY

During the past nine years the nitrogen mustard methyl-bis(beta-chloroethyl)amine (HN_2) has found a definite place in the treatment of malignant lymphomas, certain blood dyscrasias and inoperable bronchogenic carcinoma. Efforts have been made to discover a congener of nitrogen mustard that would be more effective against malignant cells and less toxic to normal cells. Recently, a new compound has been studied in the laboratory[1] and the clinic[2] which has certain advantages over nitrogen mustard HN_2 and which offers the possibility of extending the usefulness of this type of chemotherapy.

The new compound has already acquired several synonyms: triethylene melamine, TEM, and 2,4,6-triethyleneimino-*s*-triazine. It was first synthesized in Germany and used there in a commercial process for improving the finish of rayon fabrics. The chemical relationship of triethylene melamine to methyl-bis(beta-chlorethyl)amine led to the cancer chemotherapeutic investigations of the compound in England and America.

The experimental studies revealed that triethylene melamine had cytotoxic actions on normal and neoplastic cells that were qualitatively similar to the nitrogen mustards. It was further noted that the compound was active when given by mouth to experimental animals. This major advantage of triethylene melamine over the nitrogen mustard HN_2 has been demonstrated to apply to man also. The careful clinical evaluation of triethylene melamine by Karnofsky and his associates at the Memorial Center for Cancer and Allied Diseases and the report by Wright and co-workers at the Harlem Hospital have shown not only that the drug can be effectively administered by mouth but that the incidence and severity of nausea and vomiting produced is significantly less than occur with injection of nitrogen mustard. Triethylene melamine can also be given intravenously and may eventually replace methyl-bis(beta-chloroethyl)amine because of the less distressing gastrointestinal symptoms. The clinical studies indicate that triethylene melamine produces remissions in diseases that respond to nitrogen mustard and also causes leukopenia and thrombopenia completely analogous to the depressions observed after intravenously administered nitrogen mustard. The peculiar asset of the drug lies in its effectiveness after oral administration. This makes possible ambulatory management of patients and greatly facilitates the investigation of maintenance dose therapy to prolong remission intervals. Although it has not yet been conclusively demonstrated that long term treatment with small doses of triethylene melamine curtails the frequency of exacerbations in the malignant lymphomas, the evidence from Karnofsky's studies is encouraging.

Triethylene melamine will almost surely merit inclusion among the drugs available for the palliation of neoplastic diseases. The investigators who have studied this compound clearly point out, however, that the drug is effective against the same malignant diseases that respond to methyl-bis(beta-chloroethyl)amine and also that the depression of bone marrow function is similar after the administration of either agent. This emphasizes the specificity of cellular site and mechanism of action of the nitrogen mustards and triethylene melamine; these agents are related to each other, in that they both contain ethylenimino groups. On the basis of the experience with triethylene melamine and the many nitrogen mustards that have been studied in the laboratory, it may reasonably be concluded that the entire group is toxic to normal as well as to neoplastic cells.

ORGANIZATION SECTION

THE STATE JOURNAL ADVERTISING BUREAU

The State Journal Advertising Bureau, formerly the Cooperative Medical Advertising Bureau, serves 34 state medical journals, which are members of the bureau. These journals represent 42 state medical associations:

- Alabama, Journal of Med. Assn. of
- Arizona Medicine
- Arkansas Med. Society, Journal of
- Connecticut State Med. Journal
- Delaware Med. Journal
- District of Columbia Med., Annals of
- Florida Med. Assn., Journal of
- Georgia, Journal of Med. Assn. of
- Hawaii Med. Journal
- Indiana State Med. Assn., Journal of
- Iowa State Med. Soc., Journal of
- Kansas Med. Soc., Journal of
- Kentucky Med. Journal
- Maine Med. Assn., Journal of the
- Michigan State Med. Soc., Journal of
- Minnesota Medicine
- Missouri State Med. Assn., Journal of
- Nebraska State Med. Journal
- New England Journal of Med. (Mass., New Hamp.)
- New Jersey, Journal of Med. Soc. of
- New Orleans Med. and Surgical Journal
- North Carolina Med. Journal
- Northwest Medicine (Oregon, Washington, Idaho & Alaska)
- Ohio State Med. Journal
- Oklahoma State Med. Assn., Journal of
- Pennsylvania Med. Journal
- Rocky Mountain Med. Journal (Colo., Mont., New Mex., Utah, Wyo.)
- South Carolina Med. Assn., Journal of
- South Dakota Journal of Med.
- Tennessee State Med. Assn., Journal of
- Texas State Journal of Med.
- Virginia Med. Monthly
- West Virginia Med. Journal
- Wisconsin Med. Journal

Membership in the State Journal Advertising Bureau is limited to official publications of state medical societies which must adhere to the advertising standards adopted by the advisory committee for the bureau.

The bureau was established in 1913 by the Board of Trustees of the American Medical Association to assist state medical journals in securing revenue through the sale of advertising space in the journals. This assistance has provided substantial support for the state publications. For example, 1941 net sales were $151,823, while present indications for 1951 suggest a figure exceeding $641,000. On this basis, the gross sales will reach, or perhaps exceed, the $700,000 mark, a sum which should help much to defray the expenses of the member journals. The increase of the volume of business indicates clearly the value of the service provided by the bureau.

REGULATIONS FOR DIATHERMY EQUIPMENT

The office of the Council on Physical Medicine and Rehabilitation of the American Medical Association wishes to draw attention to certain regulations for medical diathermy equipment. There appeared in THE JOURNAL of Sept. 6, 1947, under the proceedings of the Council on Physical Medicine and Rehabilitation, Public Notice No. 7722, entitled "Order with Respect to Medical Diathermy and Industrial Heating Equipment and Notice of Proposed Rule Making with Respect to Miscellaneous Equipment" of the Federal Communications Commission. This document assigns three frequencies, in harmonic progression, for medical diathermy and industrial heating. The channels reserved are 13.66, 27.33 and 40.98 megacycles, corresponding to approximately 22, 11 and 7½ meters wavelength, respectively. The widths of the channels are approximately 15, 320 and 40 kilocycles, respectively. Another channel has been assigned, namely, 2,450 megacycles, corresponding roughly to 12.2 cm. wavelength. Frequencies of 915, 5,850, 10,600 and 18,000 megacycles have also been allocated for industrial, scientific and medical use.

Under these rules, apparatus either in use or manufactured prior to July 1, 1947, are exempt from the provisions of the rules for a period of five years. From July 1, 1947, provided no serious interference results from the operation of such equipment, it provides that the medical profession can continue to use uncontrolled short-wave diathermy until 1952, if the equipment does not cause serious interference. After that date the users of such equipment, old or new, must obtain approved apparatus according to the law.

The Council on Physical Medicine and Rehabilitation has on its accepted list diathermy equipment which not only meets the requirements of the Council but also carries the "type-approval" of the Federal Communications Commission. Although a year remains before the law goes into effect, the shortages of materials at the present time make it difficult for the manufacturers to provide diathermy equipment to meet the demand. The placing of orders immediately would seem advisable.

Uncontrolled short-wave diathermy apparatus cannot be changed economically to meet the rules and regulations of the Federal Communications Commission. It is possible for a qualified engineer to redesign the equipment, but the cost of labor and materials and the expense of having a representative of the Federal Trade Commission or an authorized engineer to examine it would be more than would be involved in the purchase of a new apparatus from a reliable manufacturer. A redesigned appliance must operate on one of the assigned frequencies, and the frequency must stay within the limits of tolerance under the influence of varying loads. Furthermore, the harmonic radiations should be suppressed to within the prescribed 25 microvolts per meter at a distance of a thousand feet. The radiation from an unaccepted powerful diathermy apparatus in the immediate vicinity will cause havoc in reception of television programs.

It is hoped that the critical shortage of materials will not be so great that the National Production Authority will be obliged to deprive the manufacturers of diathermy of the necessary supplies to meet the need.

MEDICAL LEGISLATION

FEDERAL

Physically Handicapped Children's Education

Senator Hill of Alabama introduced S. 1463, for himself and eight other senators. It would enable the states to make more adequate provision for special services required for the education of physically handicapped children of school age. The term "physically handicapped children" means children of school age who are crippled, blind, partially seeing, deaf, hard of hearing, defective in speech, tuberculous, epileptic, cardiopathic, or otherwise physically handicapped to such an extent that they require special services for their education. The services proposed would be designed to parallel the work being done now for crippled children under the Social Security Act.

The bill calls for an appropriation of 4 million dollars for the fiscal year ending June 30, 1952; 8 million for the fiscal year ending in 1953; 12 million for the fiscal year ending in 1954; 16 million for the fiscal year ending in 1955, and a like sum annually thereafter. These funds would be used to provide assistance to the several states to enable them to establish and develop special education services. The federal assistance would be allotted among the states on a formula in which per capita income and the number of school age children would be factors. For any state, the federal percentage could not exceed 75% nor be less than 33⅓%. States receiving federal assistance would be required to conform to minimum standards set forth in the bill. The sufficiency of state plans would be determined by the commissioner of education of the Federal Security Agency. A state would not be eligible for federal contribution for any year if the amount made available by the state and its subdivisions is less then their average expenditure for special services to the physi-

---

The summary of federal legislation was prepared by the Washington Office of the American Medical Association and the summary of state legislation by the Bureau of Legal Medicine and Legislation.

cally handicapped in the period 1947 to 1949. Expenditures of a state or its subdivisions for the purchase, maintenance, repair or rental of real estate could not be counted toward its share of the total expenditure for the program.

VA Benefits for Korea Veterans

Senate Joint Resolution 72 was introduced by Senator George of Georgia, for himself and four other senators. It provides that veterans serving on or after June 27, 1950, would be entitled to benefits of medical and hospital care, compensation, and pensions which were provided veterans of World War II. This resolution was introduced and passed by both Houses of Congress on May 10 and was signed by the President May 11, becoming Public Law No. 28. A dozen bills offering to provide similar benefits have been pending in Congress. The publication of the incident of a Korea veteran being denied hospital treatment brought this immediate action.

STATE

California

Bills Introduced.—A. 1504, to amend the Welfare and Institutions Code, proposes the addition of regulations relating to **epileptic persons** and would provide that such persons could be committed to state hospitals when they are in need of treatment or when they are suffering additionally from mental illness. A. 1579, to amend the Business and Professions Code, proposes that the regulations relating to the sale of drugs, chemicals, and medicines shall not apply to the sale of, among other things, sterilized sutures, **hypodermic needles and syringes**, medicinal gases, ether, chloroform, and ethyl chloride, injectable anesthetics of the procaine series, sulfa creams, ointments, and jellies used for introduction into the vaginal tract, where such sale is made to a physician, dentist, chiropodist, veterinarian, pharmacist, medical technician, or medical technologist, to a clinic, hospital, or other similar institution, or to an exporter.

Bills Enacted.—A. 71 has become Chapter 185 of the Laws of 1951. It amends the Business and Professions Code by establishing regulations relating to the **reinstatement of licenses** by persons serving in the armed forces. A. 1211 has become Chapter 143 of the Laws of 1951. It eliminates from the Business and Professions Code provisions relating to **midwives.** It also permits hospitals to appoint a graduate of an approved school as a resident or assistant resident for postgraduate training. A. 2674 has become Chapter 235 of the Laws of 1951. It amends the Business and Professions Code by making it a misdemeanor for an unlicensed person to **use the word "doctor,"** the letters or prefix "Dr.," the letters "M.D.," or any other term or letters indicating or implying that he is a physician, on any business card or letterhead. A. 2675 has become Chapter 318 of the Laws of 1951. It amends the Business and Professions Code by providing that applicants for the **physician's and surgeon's examination** graduating from school after Jan. 1, 1955, must present evidence of having completed a three year resident course of college grade, including the subjects of physics, chemistry, and biology, before commencing the study of medicine. A. 2676 has become Chapter 236 of the Laws of 1951. It amends the Business and Professions Code by providing that the adjudication of insanity or mental illness or the voluntary commitment or admission to a state hospital of any licentiate for a mental illness shall operate as a **suspension of the right to practice his profession** and such suspension shall continue until restoration to or declaration of sanity or mental competence. A. 2677 has become Chapter 237 of the Laws of 1951. It amends the Business and Professions Code relating to the subjects of examination for a physician's and surgeon's certificate by eliminating materia medica, pharmacology, and therapeutics and substituting therefore **pathology—gross and microscopic.** A. 2678 has become Chapter 238 of the Laws of 1951. It amends the Business and Professions Code by providing that every physician who, while in actual attendance on patients, is **intoxicated** to such an extent as to impair his ability to conduct the practice authorized by his certificate with safety to the public and his patients, shall be guilty of a misdemeanor. A. 2679 has become Chapter 239 of the Laws of 1951. It amends the Business and Professions Code relating to applicants for a physician's and surgeon's certificate whose application is based on a diploma from a **foreign medical school** by providing that in lieu of a one year internship in a hospital approved by the board, the applicant may have completed his final year of medical instruction in an approved medical school in the United States. S. 1602 has become Chapter 298 of the Laws of 1951. It authorizes the board of medical examiners to grant approval of the employment of **physicians and surgeons on a salary basis** by licensed charitable institutions, foundations, or clinics or by approved medical schools operating clinics therewith, if no charge for professional services rendered to patients is made by the institution.

Florida

Bills Introduced.—H. 520, proposes to authorize the Florida State Board of Health to make use of the **injunctive process** to restrain or prevent the violation of any statute of which the board is charged with the enforcement. H. 526, proposes that **expert witnesses** who have testified in court shall be allowed a witness fee in such reasonable amount as the trial judge may determine and that the amount of such fee shall be taxed as costs in the case. H. 579 proposes to require physicians to **register annually** with the State Board of Health. H. 635 and S. 543 propose to authorize the superintendent of any institution under the direction of the Board of Commissioners of State Institutions, when medical and dental personnel is needed but cannot be obtained in the state, to employ competent, **experienced, medical or dental personnel** from outside of the state. Such personnel would not be required to be examined and licensed to practice their profession, so long as they are engaged exclusively on the medical or dental staff of such institution and do not engage in private practice within the state. S. 492 and H. 605 propose that either the state attorney or the county solicitor may have **autopsies** performed on dead bodies found within the county, before internment, whenever in the opinion of such person such autopsies are necessary to ascertain whether death resulted from a criminal act or as the result of criminal negligence. The proposal would also provide that the reasonable charges of physicians performing such autopsies should be paid from the County General Fund.

Bills Enacted.—H. 90 became law without approval May 9, 1951. It amends the medical practice act by requiring applicants for a license to be **citizens of the United States.** (Previously it was permissable for them to show that they had filed a declaration of intention to become a citizen.) It also permits the board to accept evidence from the applicant that he has received training in hospitals sufficient to bring his medical education up to a standard equivalent to that of graduates of approved medical schools in the event that the applicant is not such a graduate. H. 91 became law without approval May 9, 1951. It amends the medical practice act by authorizing the board to pass on the **good standing and reputability of any hospital** and to determine those that maintain a standard of training sufficient to be recognized by the board when considering medical examinations given by the board. H. 93 became law without approval May 9, 1951. It amends the medical practice act by providing that when a person has been adjudicated insane he shall be deemed **disqualified to practice medicine** so long as such adjudication shall remain in full force and effect. H. 94 became law without approval May 9, 1951. It amends the **medical practice act** by exempting therefrom optometrists and pharmacists duly licensed by their respective state boards and also persons furnishing medical assistance in case of emergency. The law further sets forth regulations relating to the registration of every graduate of a medical school and every person practicing as a resident physician, assistant resident physician or intern in any hospital in the state. No person is permitted to be employed or act as a resident physician, assistant resident physician, or intern who has not so registered. H. 96 became law without approval May 9, 1951. It provides that a **certificate by the board of medical examiners**, board of osteopathic medical examiners, board of chiropractic examiners, board of naturopathic examiners, board of optometry, board of examiners for nurses, board of pharmacy, or board of dental examiners, certifying that the records of such board evidence, or fail to evidence, the issuance of any license to practice any of such professions shall be admissible in all courts and may be impeached only by positive documentary evidence or testimony of not less than two witnesses.

Illinois

Bills Introduced.—H. R. 65, proposes the creation of a committee to investigate the need for and the desirability of a state institution for **narcotic addicts.** H. 872, proposes to authorize the Department of Registration and Education to license persons desiring to practice **physiotherapy,** which is defined as the method, art, or science of treating the human body for hygienic or remedial purposes by the following methods: massage and manipulations with the hands or with any other physiotherapy modality, and the use of such adjuncts as light, heat, air, water, diet, gymnastics, and electricity. S. R. 53, proposes the creation of a committee to make an investigation relating to the establishment of a hospital in Chicago for the treatment of acute mental patients, especially those addicted to the habitual use of **narcotics and alcohol.**

Massachusetts

Bills Introduced.—H. 2455, proposes regulations for the licensing of persons desiring to conduct a **dispensary.** H. 2468, proposes to authorize the Board of Registration in Medicine to issue licenses and to regulate the practice of **physical therapy,** which is defined to mean the treatment of any bodily or mental condition of any person by the use of the physical, chemical, and other properties of heat, light, water, electricity, massage, and active and passive exercise. The use of roentgen rays and radium for diagnostic and therapeutic purposes and the use of electricity for surgical purposes, including cauterization, would not be permitted under the proposal.

Bill Enacted.—H. 2310 has become Resolution Chapter 11 of the Laws of 1951. It directs the Judicial council to investigate relative to the existing statutes relating to **alcoholism.**

Texas

Bill Enacted.—H. 47, was approved May 3, 1951. It provides for the creation of a **board of vocational nurse examiners** and defines a licensed vocational nurse as a person who directly attends or cares for the sick for compensation or hire, and whose personal qualifications, preliminary education, or nursing education in biological, physical, and social sciences will not qualify that person to become certified as a professional registered nurse.

Vermont

Bill Enacted.—S. 39, was approved April 27, 1951. It eliminates from membership on the **state board of medical registration** the two homeopathic physicians who were previously required to be members thereof.

Wisconsin

Bill Enacted.—S. 374 has become Chapter 120 of the Laws of 1951. It authorizes the board of medical examiners to issue licenses to practice medicine and surgery or osteopathy and surgery and to accept, in lieu of its own examination, the certificate of the **national board of medical examiners.**

MEDICAL NEWS

COLORADO

Annual Alumni Session.—The Medical Alumni Association of the University of Colorado School of Medicine, Denver, will hold its 26th annual session on June 1-2. The annual senior-alumni baseball game and annual banquet climax the two-day meeting. The second annual Colorado Intern-Resident Clinics on June 4-5 have been arranged by an intern-resident committee. Dr. Robert M. Zollinger, professor and chairman of the department of surgery at Ohio State University College of Medicine, Columbus, will be the guest surgeon and lecturer and will deliver the second annual intern-resident lecture on "Recent Advances in Burn Therapy." The afternoon sessions will consist of 18 papers by the resident staff.

CONNECTICUT

Summer School of Alcohol Studies.—The ninth annual session of the summer school of alcohol studies will be held at Yale University July 7-Aug. 3 under the direction of Selden D. Bacon, director of Yale's section on alcohol studies. Registration for this year's session will take place July 7-8 with the first lecture and a reception planned for the night of July 8. Dr. Howard W. Haggard, director, Yale Laboratory of Applied Physiology, will be the initial speaker. The curriculum is divided into four phases and consists of 62 lectures, 15 hours of seminars, informal group meetings, visits to the laboratory, clinic and other facilities, and individual consultations with staff members. The four major divisions of the curriculum are: (1) orientation, with emphasis on scientific methods as applied to problems of alcohol; (2) physiology, psychology and cultural sociology in relation to alcoholic beverages; (3) the major problem areas, and (4) description and analysis of responses to these problems. Since the school's inception in 1943 over 1,160 persons have completed the course. Students from every state in the United States, most of the Canadian provinces, and countries in Central and South America, Europe and the Orient are among the graduates. Academic credit for students can be obtained through arrangement with the degree-granting authority of the institution with which the student is registered. Correspondence should be addressed to: Summer School of Alcohol Studies, Laboratory of Applied Physiology, Yale University, 52 Hillhouse Ave., New Haven, Conn.

Dr. Braceland Joins Institute of Living.—Dr. Francis James Braceland, consultant in psychiatry at the Mayo Clinic, Rochester, Minn., has been named psychiatrist-in-chief of the Institute of Living. Dr. Braceland, at present secretary and treasurer of the American Board of Psychiatry, has been a fellow and clinical director of the Pennsylvania Hospital, Department for Mental and Nervous Diseases, Philadelphia. He has been successively associate professor of psychiatry, Women's Medical College, Philadelphia, assistant professor of psychiatry, graduate school, University of Pennsylvania, Philadelphia, and dean and professor of psychiatry at Loyola University School of Medicine, Chicago. During World War II he was a special assistant in psychiatry to the Surgeon General of the U. S. Navy and later chief of the division of neuropsychiatry, Bureau of Medicine and Surgery.

DISTRICT OF COLUMBIA

Course in Sight Saving and Braille.—A special summer course will be held at the Catholic University of America, Washington, D. C., July 2 through Aug. 11 to train teachers of sight saving classes and teachers of Braille classes. A clinic and lectures by outstanding ophthalmologists, observation, and Braille teaching classes make up the course. Address inquiries to Roy J. Deferrari, Office of the Secretary-General, Catholic University of America, Washington 17, D. C.

ILLINOIS

Rabies Quarantine.—The state department of agriculture imposed a rabies quarantine in Benton, Franklin County, after three children and four adults were given Pasteur treatments after being bitten or otherwise exposed to two rabid dogs. During April and early May, 53 persons in West Frankfort were compelled to take Pasteur anti-rabic treatments. At least 20 persons reportedly had been exposed to the disease in nearby Williamson County, which is also under quarantine.

Cancer Symposium.—A cancer symposium was held at the Herrin state diagnostic cancer clinic on May 17 for the physicians of the Ninth and Tenth districts of the Illinois State Medical Society. The program was arranged in cooperation with the American Cancer Society, the division of cancer control of the state department of public health, and the American Academy of General Practice. The program, beginning at 1:30 p. m., was as follows:

John B. Frerichs, St. Louis, Cytology of Cancer and the General Practitioner.
Chester C. Guy, Chicago, Tumors of the Biliary Tract.
Helmut P. Seckel, Chicago, Malignant Tumors in Children.
Leo J. Brown and Friedrich P. Bornstein, Herrin, Case Presentations from the Herrin Hospital Cancer Clinic.

Dr. Paul C. Bucy of the University of Illinois College of Medicine, Chicago, spoke at the dinner at the LyMar Hotel at 7:30 p. m. on "Early Diagnosis of Intracranial Lesions."

Chicago

New Head of Tumor Institute.—Dr. James T. Case, radiologist, has been named president of the Chicago Tumor Institute succeeding Dr. Ludvig Hektoen, who has been elected president emeritus.

Multiple Sclerosis Research.—On May 31 the Multiple Sclerosis Foundation presented the first installment of a five-year $125,000 grant for basic research to Northwestern University Medical School. The fund will establish the first research program in the Middle West for multiple sclerosis.

Course in Techniques in Virology.—An eight-week summer course for bacteriologists interested in gaining laboratory experience in basic techniques in virology will be offered by the University of Illinois, Chicago Professional Colleges, June 25-Aug. 18. It will be given under the direction of Dr. John E. Kempf, associate professor of bacteriology. Graduate credit will be awarded for satisfactory completion of the course. Requirements for admission are a bachelor's degree, basic course work in bacteriology, and qualifications for registration in the graduate college of the university. The tuition is $17.50 for residents of Illinois. Requests for information should be addressed to Dr. Milan V. Novak, Associate Dean of the Graduate College, Chicago Professional Colleges, University of Illinois, 808 S. Wood St., Chicago 12.

IOWA

Society News.—The Polk County Medical Society concluded its current program year April 18 with a Cancer Institute at the Hotel Savery in Des Moines. Visiting speakers included: Drs. Charles L. Eckert, Washington, D. C.; Joseph H. Burchenal, New York; Harold L. Stewart, Bethesda, Md., and Walter L. Palmer, Chicago.

Memorial Library for Doctor Wilkins.—Since the death of Dr. Donald Wilkins of Ames in Korea Oct. 5, 1950, a number of his colleagues and friends have planned to create a memorial to him in the form of a library fund to establish and build a collection of books, journals, and reprints on anesthesiology. The fund will be called the Wilkins Memorial Library Fund. Any of Dr. Wilkins' friends who desire further information with reference to this fund or to contribute to it should write Dr. Stuart C. Cullen, Chairman, Division of Anesthesiology, University Hospitals, Iowa City.

Physicians are invited to send to this department items of news of general interest, for example, those relating to society activities, new hospitals, education and public health. Programs should be received at least three weeks before the date of meeting.

KENTUCKY

Mental Hygiene Committee.—An Advisory Committee on Mental Hygiene to assist in the improvement of the mental hospital treatment program has been appointed by Governor Wetherby. Members of the committee, of which Dr. S. Spaford Ackerly, Louisville, is chairman, are Drs. Bruce Underwood, Louisville; John H. Rompf, Lexington, and Robert Charles Smith, Newport.

Health Official Appointed.—Dr. Charles E. Reddick assumed his duties as deputy state health commissioner and director of local health services for the state department of health April 16. He is a former Paducah-McCracken county health officer and comes to his new position from the Arizona Department of Health, Phoenix, where he has served as director of local health administration for the past three years. Dr. Reddick succeeds Dr. Harold M. Kelso, who resigned January 1 to return to Knoxville, Tenn., as assistant city health officer.

MASSACHUSETTS

Personal.—Dr. Samuel A. Levine, clinical professor of medicine at Harvard Medical School, Boston, and member of the senior staff of the Peter Bent Brigham Hospital, Boston, served as professor of medicine "Pro Tem" at Georgetown University School of Medicine, Washington, D. C., April 1-7. The program was devoted to informal ward rounds and small group teaching for the senior medical students and the house staff.

State Institute of Laboratories.—Dr. Johannes Ipsen of the Harvard School of Public Health has been appointed superintendent of the newly-formed Massachusetts Institute of Laboratories, which will contain four state-operated laboratories under one administration. The state public health department has long provided free diagnostic and other direct services to physicians and local boards of health through its four laboratories. The four laboratories now combined into one institute are: (1) the diagnostic laboratory under Dr. Robert A. MacCready; (2) the biological laboratory, directed by James A. McComb; (3) the Wassermann Laboratory, directed by Dr. William A. Hinton, and (4) the blood laboratory. All four are located on South Street, Jamaica Plain. Dr. Ipsen in 1938 became director of the League of Nations' department of biological standards, where he was responsible for setting and maintaining standards of vaccines and serums all over the world for the League of Nations. He held this post until 1947, when the United Nations' World Health Organization took over this work.

MICHIGAN

Upper Peninsula Medical Society Meeting.—The Marquette-Alger County Medical Society will be host to the Upper Peninsula Medical Society, meeting in Marquette June 22-24. Guest speakers at the session will include:

M. Edward Davis, Chicago, Recent Advances in Diagnosis and Treatment of Carcinoma of the Uterus.
Frederick Schreiber, Detroit, Head Injuries.
George J. Curry, Flint, Recent Advances in Treatment of Ankle Injuries.
Harry R. Foerster, Milwaukee, Dermatology.
Robert L. Parker, Rochester, Minn., Cardiology.
Harry A. Towsley, Ann Arbor, Pediatrics.
Gordon B. Myers, Detroit, Disturbances of Blood Potassium.
Oliver H. Beahrs, Rochester, Minn., Carcinoma of the Thyroid.
Rudolf J. Noer, Detroit, Gastro-Intestinal Hemorrhage.
John M. Sheldon, Ann Arbor, Allergy in General Practice.
Samuel W. Hartwell, Lansing, Office Mental Hygiene.

The Woman's Auxiliary will meet in conjunction with the society. The annual banquet will be held Saturday at 7 p. m. Technical exhibits will be shown.

Annual Conference on Aging.—The University of Michigan announces its fourth annual Conference on Aging will be held in Ann Arbor July 11-13. Rehabilitation of the older handicapped person will be the topic of this year's conference. American and foreign authorities will discuss questions raised at the meetings. Attention will be directed to medical, psychosocial, economic, and vocational aspects of retaining the over-40 workers in the labor force and the role of these workers with reference to mobilization. The conference is under the cosponsorship of the Institute for Human Adjustment, school of medicine, school of public health and extension service of the University of Michigan, the Office of Vocational Rehabilitation of the Federal Security Agency, and the Michigan Department of Vocational Rehabilitation. Room reservations should be made by writing to the Michigan Union, Ann Arbor. For further information write to Dr. Wilma Donahue, Institute for Human Adjustment, Room 1510, Rackham Building, Ann Arbor.

MISSOURI

Friends Honor 50-Year Practitioner.—More than 1,000 persons attended a reception in Kansas City in honor of Dr. Max Goldman, who has practiced medicine for 50 years. Earlier the staff of St. Mary's Hospital presented him a gold medal that bore an engraving of the hospital and an inscription of appreciation.

State Medical Election.—The Missouri State Medical Association at its meeting in Kansas City April 22-25 installed Dr. C. Edgar Virden, Kansas City, as president. Other officers for the coming year include: J. William Thompson, St. Louis, president-elect; H. E. Petersen, St. Joseph, secretary, and Charles E. Hyndman, St. Louis, treasurer. Delegates to the American Medical Association are Drs. Robert E. Schlueter, St. Louis, and James R. McVay, Kansas City. Their respective alternates are Drs. Flavius G. Pernoud, St. Louis, and Rolla B. Wray, Nevada.

NEW YORK

Cerebral Palsy Center.—The Nassau County Cerebral Association broke ground May 6 for its $225,000 cerebral palsy diagnostic and treatment center at Roosevelt, L. I. The association now operates a temporary palsy center in the Hempstead American Legion building.

Anesthetists Placement Committee.—The Placement Committee of the New York State Society of Anesthesiologists, under the chairmanship of Dr. Philip H. Sechzer, Laurelton, will function as a central clearing house and counseling service for physicians, groups and institutions. The society office is at 137 W. 11th St., New York 11, N. Y. The committee will determine vacancies in the state open to anesthesiologists. The state will be surveyed to discover localities where no professional service in anesthesia is available. The committee will be available for consultation with any physician who intends to practice anesthesiology within New York State.

Medical Jurisprudence Society.—The Society of Medical Jurisprudence held a meeting at 8:30 p. m. May 14 in room 440 of the New York Academy of Medicine building. Col. Howard J. Hutter, instructor in radiology, New York University-Bellevue Medical Center, New York, presented a paper on "How to 'Read' an X-Ray Film." This was followed by a discussion from the medical expert's standpoint by Dr. Solomon Fineman, assistant clinical professor of radiology at Columbia University, New York, who also spoke on pitfalls in x-ray diagnosis. Dr. Frank R. Ferlaino, assistant clinical professor of industrial medicine at New York Post-Graduate Hospital and Dispensary, discussed the paper from the industrial and liability examiner's standpoint. The meeting was open for members and their guests.

New York City

Research on Bacteriophage.—A grant of $50,000 has been received by the Roosevelt Hospital to support a five year research program in the field of bacteriophage. The money will be disbursed at the rate of $10,000 a year. The donor requested that the gift be anonymous. Dr. Simon A. Beisler, president of the hospital's medical board and head of the division of urology, will guide the project to develop a phage.

Infirmary Postgraduate Courses.—The complete reorganization of postgraduate courses at the New York Eye and Ear Infirmary has been accomplished, under the direction of Dr. Raymond E. Meek, chairman, and Dr. J. Gordon Cole, secretary-treasurer. Postgraduate courses for both eye and ear specialists are given throughout the year and are available for a limited number of students applying to the registrar at the infirmary.

Dr. Schaefer to Receive Remington Medal.—Hugo H. Schaefer, Ph.D., treasurer of the American Pharmaceutical Association and dean of the Brooklyn College of Pharmacy, will receive pharmacy's highest honor, the Remington Medal, at a dinner in New York in the fall. The past presidents of the American Pharmaceutical Association served as the jury of award. Dr. Schaefer was commended for his unselfish service to the profession over the past 30 years. He was cited for his leadership in the development of sound educational procedures in American pharmacy, his contributions to the work of the U. S. Pharmacopoeia and National Formulary revision, his contributions to the solution of problems involving food and drug legislation, and his public service as chemist to the New York Board of Pharmacy and adviser to the War Production Board in World War II.

Grant for City Day Camps.—The New York Fund for Children, Inc., has made a grant of $30,000 to the New York City Department of Health to finance department activities in relation to improving conditions for children in day camps. There were about 280 camps operating in and around the city last summer, and from 75,000 to 100,000 children attended. In city day camps children live at home and attend the camp, usually six or eight hours a day. The grant will be used toward: (1) Inspection of camps to eliminate unsanitary and other undesirable practices; (2) educational efforts with camp operators, directors, and other personnel aimed at developing and gaining acceptance of higher standards for camps; (3) educational efforts with parents (through publicity in newspapers, by radio, with pamphlets and so on) to help them select day camps for their children, and (4) stimulating an interest in local universities and colleges in health problems involving the operation of day camps.

NORTH CAROLINA

Postgraduate Course.—The Duke University School of Medicine's spring medical postgraduate course will be held in Durham June 18-21. Papers will be given during the morning sessions, ward rounds or visits to clinics will be held in the afternoons. Round table discussions on Monday and Tuesday evenings will be devoted to the use of drugs in cardiovascular diseases and pain.

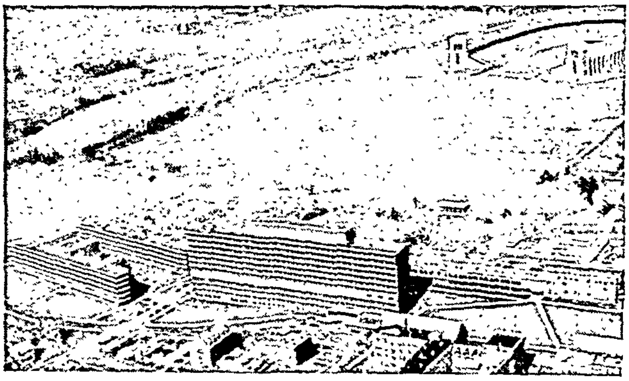
OHIO

Society News.—The recently-organized Cleveland Society of Physical Medicine and Rehabilitation has elected the following officers: Dr. Shelby G. Gamble, Cleveland, president; Dr. Harry T. Zankel, Cleveland, vice president, and Dr. Bert A. Treister, University Heights, secretary-treasurer.

State Medical Election.—At the April meeting of the Ohio State Medical Association in Cincinnati Dr. Fred W. Dixon, Cleveland Heights, was installed as president, and Dr. Harve M. Clodfelter, Columbus, was chosen president-elect. Dr. Henry P. Worstell, Columbus, was elected treasurer in 1949 for a three-year term. The 1952 meeting will be held in Cleveland May 20-22.

Dr. Lotspeich to Head Department of Physiology.—A 1944 honor graduate of the University of Cincinnati College of Medicine, Dr. William D. Lotspeich, physiologist, finishing a fellowship at Oxford University, England, will return to his alma mater next September as head of the department of physiology. He will succeed Dr. Martin H. Fischer, now professor emeritus of physiology. Dr. Gustav Eckstein, associate professor of physiology, has been acting department head. Dr. Lotspeich was appointed instructor in physiology at Cornell University Medical School, New York, in 1945, then went to the University of Syracuse Medical School as an assistant professor of physiology. Since 1948 he has held a scholarship in medical sciences from the John and Mary R. Markle Foundation.

Dedicate Health Center at Columbus.—The new health center at the Ohio State University was dedicated at outdoor ceremonies May 15. Top officials of the university and state welfare and health departments participated in the ceremonies. Dr. Raymond B. Allen, president of the University of Washington at Seattle, delivered the dedication address. The four buildings in the 15½ million dollar center are the Dentistry Building, the Ohio Tuberculosis Hospital, under the state health department, the 600-bed University Hospital, and the Columbus Receiving Hospital, under the state welfare department. Outstanding alumni of the colleges of medicine and dentistry were presented with awards in recognition of contributions to their respective fields, the first such awards given by the two colleges. Those receiving medical alumni awards were: Drs. Jonathan Forman and Herbert M. Platter, both of Columbus; Dr. Joseph H. McNinch, Washington, D. C.; Dr. James C. Sargent, Milwaukee, and Dr. Alfred H. Whittaker, Detroit. Scientific sessions of physicians and dentists and conferences of nurses were scheduled for the week. The new University Hospital is a single-line building, 400 feet long and 50 feet wide consisting of 12 floors. Its length was determined by typical nursing floors consisting of three nursing units of approximately 30 beds each. The majority of the wards run continuously along the south side of the corridor. Beds are proportioned on the basis of approximately 11 per cent in single rooms, 50 per cent in double rooms, and 39 per cent in four-bed rooms. Floors six through eleven contain the patient rooms. The operating rooms and adjunct services and laboratories are located on the fourth floor. One operating room is equipped with louvers in the ceiling through which color movies may be taken. The room is also equipped with conduits for televising the operations. On the operating floor is a clinical observation and lecture room with a "one-way" observation panel into one of the 12 operating rooms. The third floor is devoted to diagnostic laboratories serving the needs of the entire center. The second floor contains the departments of radiology and physical therapy, which will give complete service to the general hospital patients. These lower floors are accessible to students and to patients from adjacent hospitals without passing through the hospital wards. Administrative offices are located on the first floor, while the emergency rooms, receiving, supplies, storage, and kitchen are on the ground floor. The administration of the various buildings in the program is under separate college or state departments, but all are a coordinated part of the health center. Space vacated in Hamilton Hall by the college of dentistry, which has moved to its new building in the health center, is being utilized and enlarged for the increased enrollment in the college of medicine.



The four new buildings of the 15½ million dollar health center at Ohio State University: (1) Ohio Tuberculosis Hospital; (2) Columbus Receiving Hospital; (3) University Hospital, and (4) Dentistry Building.

PENNSYLVANIA

Society News.—The George F. Geisinger Memorial Hospital and the Foss Clinic at Danville conducted a postgraduate seminar April 20. Among the speakers was Dr. Russell E. Teague, Philadelphia, secretary of health of Pennsylvania, who spoke on state public health problems.

Clean Streams Program.—Nine additional municipalities have received a total of over $96,770 from state funds as part payment of the cost of preparing plans for sewage treatment works under the state's clean streams program. The latest municipalities to receive checks are Scranton, North York, Christiana, Millerstown, Galeton, Clearfield, Nanticoke, Honesdale and

Coudersport. These payments bring the total paid to 189 municipalities to $1,035,148.87. Under the clean streams program payments of up to 50 per cent of the cost of plans for sewage treatment works are paid municipalities from state funds. Payments are figured on costs that prevailed in 1942, in accordance with the clean streams law.

Philadelphia

Chapin Medal Award.—Dr. Hobart A. Reimann, head, department of experimental medicine of Jefferson Medical College of Philadelphia, delivered the 10th Charles V. Chapin oration May 9 and received the Chapin Medal awarded by the City of Providence and the Rhode Island Medical Society in Providence. The medal is awarded annually to a physician who has made important contributions to medical knowledge. The present recipient was recognized for his pioneer work on the viral pneumonias, viral dysentery, and other diseases.

Pittsburgh

New Department of Biochemistry and Nutrition.—A department of biological chemistry and nutrition has been organized at the University of Pittsburgh Graduate School of Public Health, with Robert E. Olson, Ph.D., as professor and head and as lecturer in the department of medicine in the school of medicine. The department, in addition to its teaching responsibility, will have a program of basic research that will center initially around the study of cellular physiology, with particular attention to the study of tissue enzymes and of the vitamin-enzyme-hormone interrelationships in cellular metabolism. For two years Dr. Olson has been a research fellow and then an established investigator of the American Heart Association and director of the heart metabolism section, department of nutrition, at the Harvard School of Public Health, Boston. He is to receive his medical degree from Harvard in June of this year. Dr. Olson will not assume his duties on a full time basis at the University of Pittsburgh until July 1, 1952, but during the coming year he will supervise the installation of laboratory facilities and recruit key members of his staff.

TENNESSEE

Dr. Pride Made Professor Emeritus.—The University of Tennessee College of Medicine, Memphis, recently awarded Dr. William T. Pride the title of professor emeritus. Dr. Pride joined the faculty of the old College of Physicians and Surgeons in 1908 and had been professor of obstetrics and gynecology since 1933.

New Section on Clinical Chemistry.—Dempsie B. Morrison, Ph.D., associate professor of chemistry at the University of Tennessee Medical Units, Memphis, will be the director of the section of clinical chemistry to be established by the college of medicine this summer. The section is being established to enlarge both the teaching program of the college and the chemical diagnostic services to patients at John Gaston Hospital, the teaching hospital of the college. The section will be located on the second floor of the old pathology building in the rear of the hospital. The building will be remodeled as soon as the division of pathology and bacteriology moves into the new Institute of Pathology, about July 1.

WASHINGTON

Institute for Study of Acohol.—The first Northwest Institute for the Scientific Study of Alcohol will be held June 11-15 in Guggenheim Hall at the University of Washington School of Medicine, Seattle. A special medical seminar on problems of alcohol will be held June 13 for practicing physicians. Dr. Andrew C. Ivy, vice president of the University of Illinois in charge of Chicago Professional Colleges, and Elvin M. Jellinek, Sc.D., dean of the Yale Institute of Alcohol Studies in the Southwest, Texas Christian University, Dallas, will speak. Physicians may register either for the entire institute or for the seminar. Other visiting lecturers will be: Dr. Haven Emerson, New York; Leon A. Greenberg, Ph.D., New Haven, Conn.; William R. McKay, Los Angeles, and Capt. James D. Whitall, Philadelphia. The fee for the entire institute is $15 and for the medical seminar only $5.

GENERAL

Today's Health Wins Award.—*Today's Health*, published by the American Medical Association, was one of six general magazines to be voted the National Safety Council's Public Interest Award for 1950 in recognition of exceptional service to safety. During the year the magazine carried 17 major articles on safety, eight separate items, and in March inaugurated a regular monthly feature, "First Aid." The publication received the same award in 1949.

Rocky Mountain Spotted Fever.—Rocky Mountain spotted fever in the mountain and Pacific states in the past has appeared in March and has reached a peak in May or June. In the five-year period 1933-37 the average number of cases reported in March was 11 and in April 45. In the five-year period 1940-44 the average number of cases in March and April was six and 29, respectively. In March of the present year only one case was reported, and in April none was reported in these groups of states. The disease appears and reaches a peak one to two months later in the eastern part of the country.

Society of Biological Psychiatry.—This society will hold its annual meeting at the Trimble Hall in the Hotel Claridge in Atlantic City, N. J., June 17. Papers to be delivered by invitation include:

Clarence W. Olsen, Beverly Hills, Calif., Relationship Between Psychoses and Visceral Crises.
William J. Grace and David T. Graham, New York, Specificity of the Relation Between Attitudes and Diseases.
N. Dorin Ischlondsky, New York, Brain Dynamics and Psychic Activity.
Charles M. Pomerat, Chicago, Tissue Culture of the Human Brain.

The president's reception and dinner will be held at 6 p. m. for physicians and invited guests. The evening's session will be a symposium on the anatomy and physiology of thought processes.

International Congress of Allergy.—The first International Congress of the International Association of Allergists will meet in Zurich, Switzerland, Sept. 23-29. Topics under discussion include: nature and social importance of the allergic diseases, histology of the allergic lesion, chemical and serological aspects of allergy, influence of constitution and heredity on the manifestation of allergic diseases, pharmacology of allergic reactions, and diagnosis of allergic diseases. The congress will be followed on Oct. 1 and 2 by a symposium, "The Influence of the Pituitary Gland and Adrenal Cortex on Biological Reactions," which has been arranged by the Swiss Academy of Medical Sciences. The general secretary of the congress is Dr. A. S. Grumbach, Institute of Hygiene, Zurich.

International Congress of Anesthesiology.—An International Congress of Anesthesiology, organized by the French Association of Studies on Anesthesia and Anesthesiology under the patronage of the Council on Coordination of International Congresses of Medical Sciences, will be held in Paris Sept. 20-22 at the Nursing School of the Salpetriere, 47 Boul. de l'Hospital. The congress will be open to all persons interested in anesthesia. The scientific program includes:

M. Cara, Paris, Graphic Recording of Physiological Functions in the Course of Anesthesia.
M. Van de Walle, Louvain, Natural Curare Derivatives.
M. Bovet, Rome, and M. Huguenaud, Paris, Synthetic Curare Compounds; Theoretical Report; Clinical Application.
M. Thalheimer, Paris, Establishment of an International Movement of Study on Anesthesiology.

Information as to registration may be obtained from the office of the secretary of the congress, 12 Rue de Seine, Paris 6e, France.

Society Elections.—The American Society for Clinical Investigation at its meeting April 30 elected Dr. W. Barry Wood Jr., St. Louis, president; Dr. Charles A. Janeway, Boston, vice president, and Dr. William M. M. Kirby, San Francisco, secretary-treasurer.——The Council of New England State Medical Societies at their April meeting elected Dr. Joseph H. Howard, Connecticut, president; Dr. Deering G. Smith, New Hampshire, vice president, and Dr. Creighton Barker, Connecticut, executive secretary-tresaurer.——At the meeting of the American Academy of Neurology at Virginia Beach on

April 11 and 12 Dr. Pearce Bailey of Washington, D. C., became president. Newly elected officers include: Dr. Howard D. Fabing of Cincinnati, president-elect; Dr. Walter O. Klingman, Charlottesville, Va., vice president; Dr. Joe R. Brown, Minneapolis, treasurer, and Dr. Francis M. Forster, Washington, D. C., secretary. The 1952 meeting will be held in the Brown Hotel, Louisville, April 24 and 25. Next year the two-day course in neuropathology instituted this year will be given again and also a course in neuroroentgenography and electroencephalography. Requests for papers on the program are to be sent to Dr. Alexander T. Ross at the University of Indiana School of Medicine, Indianapolis. Requests must be accompanied by a title and an abstract. The deadline for this is November 1.

Rehabilitation Meeting.—The Association for Physical and Mental Rehabilitation will hold its fifth annual national convention July 3-6 in Los Angeles. The scientific and clinical sessions, to be held at the Hollywood Roosevelt Hotel in Hollywood, tentatively include Dr. Edward D. Greenwood, Menninger Foundation, Topeka, Kan.; Dr. Alvin B. C. Knudson and Dr. John E. Davis, Veterans Administration central office, Washington, D. C.; Dr. Tracy J. Putnam, Beverly Hills, Calif.; representatives from the surgeon general's office of the armed forces, and rehabilitation specialists from the University of California School of Medicine at Los Angeles, the Kabat-Kaiser Institute, Santa Monica, Calif., and a number of hospitals throughout the country. These meetings will provide an opportunity for hospital therapists and rehabilitation workers to discuss trends and research findings in medical rehabilitation. Information may be obtained from the convention chairman, Mr. Burr S. Zachary, Neuropsychiatric Hospital, Los Angeles 25, or the national president, Mr. George Devins, Veterans Administration Hospital, Long Beach, Calif.

Poliomyelitis Training Courses.—The National Foundation for Infantile Paralysis has listed the following training centers that have scheduled short courses for physicians in the treatment of poliomyelitis patients.

Children's Medical Center, Boston, Dr. William T. Green, director, June 4-8, Aug. 6-10.

D. T. Watson School of Physiatrics, Leetsdale, Pa., Dr. Jessie Wright, director, six-day courses, dates to be arranged according to number and time of applications.

Georgia Warm Springs Foundation, Warm Springs, Ga., Dr. Robert L. Bennett, director, one-week course starting the first week in July and October.

Orthopaedic Hospital, Los Angeles, Dr. Charles L. Lowman, director, May 21-24, Oct. 22-25.

Stanford University School of Medicine, San Francisco, Dr. William H. Northway, director, one course scheduled in the summer, probably in June.

University of Colorado Medical Center, Denver, Dr. Winona G. Campbell, director, May 7-9, poliomyelitis; Dec. 13-15, postgraduate course in poliomyelitis in conjunction with other pediatric problems.

Enrollment must be arranged directly with the training center. Physicians who need financial assistance to attend these polio courses should contact their local chapters of the national foundation.

CANADA

Annual Canadian Medical Meeting.—The Canadian Medical Association will hold its annual meeting in Montreal June 18-22 under the presidency of Dr. Norman H. Gosse of Halifax. A series of roundtable conferences have been arranged for Wednesday, Thursday and Friday mornings, to be followed by general sessions. Visiting speakers include, Drs. Donald C. Balfour, Rochester, Minn.; Chester S. Keefer, Boston and Charles P. Bailey, Philadelphia. Sectional meetings will be held during the afternoons. A color television program will be shown Wednesday, Thursday and Friday afternoons. A program of entertainment has been planned for the doctors' wives.

Graduate Course in Allergy.—This course will be offered by the American Academy of Allergy June 14-16 in Montreal, under the sponsorship of the Faculty of Medicine, McGill University, and will be given in the Royal Victoria Hospital. Any interested physician in the United States or Canada may attend. The fee is $40. Applications may be sent to Dr. Bram Rose at the hospital, Montreal 2, Canada. Sixteen speakers will present the course. Nine are on the university faculty: Drs. Bram Rose, John S. L. Browne, William J. McNally, Joseph A. P. Pare, G. Lyman Duff, Harry L. Bacal, H. S. Mitchell, Dr. Karl K. Pump, and Eric Wittkower; from Columbia University College of Physicians and Surgeons, New York, Elvin A. Kabat, Ph.D., and Dr. William B. Sherman. Other speakers are Dr. Hans Selye, University of Montreal; Dr. John D. L. Fitzgerald, University of Toronto; Charles H. Walton, University of Manitoba, and Rubin Gdoli, Brooklyn. In addition to general allergy subjects there will be lectures on Oto-Rhinology in Relation to Allergy, Allergic Dermatoses, Allergy in Children, and Psychiatric Aspects in Allergy.

CORRECTION

Faculty Promotions at Temple University.—Dr. John Lansbury was promoted from associate professor to clinical professor of medicine at Temple University School of Medicine, Philadelphia, not from clinical professor to professor of medicine as was stated in The Journal Feb. 3, page 333.

MEETINGS

American Medical Association, Atlantic City, June 11 to 15. Dr. George F. Lull, 535 N. Dearborn St., Chicago 10, Secretary.

American Association for the Study of Neoplastic Diseases, St. Agnes Hospital, Baltimore, June 7-9. Dr. Eugene R. Whitmore, 2139 Wyoming Ave. N. W., Washington 8, D. C., Secretary.

American College of Chest Physicians, Atlantic City, June 7-10. Mr. Murray Kornfeld, 500 N. Dearborn St., Chicago 10, Executive Secretary.

American College of Radiology, Atlantic City, June 10. Mr. W. C. Stronach, 20 N. Wacker Drive, Chicago 6, Executive Secretary.

American Diabetes Association, Chalfonte-Haddon Hall, Atlantic City, June 9-10. Dr. John A. Reed, 11 W. 42d St., New York 18, Secretary.

American Electroencephalographic Society, Hotel Claridge, Atlantic City, June 16-17. Dr. John A. Abbott, Massachusetts General Hospital, Boston 14, Secretary.

American Gastro-Enterological Association, Atlantic City, June 8-9. Dr. Dwight L. Wilbur, 655 Sutter St., San Francisco 2, Secretary.

American Geriatrics Society, Hotel Brighton, Atlantic City, June 7-9. Dr. Malford W. Thewlis, 25 Mechanic St., Wakefield, R. I., Secretary.

American Hearing Society, Palmer House, Chicago, June 29. Mrs. Frances E. Lee, 817 Fourteenth St. N.W., Washington 5, D. C., Secretary.

American Medical Women's Association, Hotel Dennis, Atlantic City, June 9-10. Dr. Mildred C. J. Pfeiffer, Woman's Medical College of Pennsylvania, Philadelphia 29, Secretary.

American Neurological Association, Atlantic City, June 18-20. Dr. H. Houston Merritt, 710 W. 168th St., New York 32, Secretary.

American Ophthalmological Society, The Greenbrier, White Sulphur Springs, W. Va., June 7-9. Dr. Maynard C. Wheeler, 30 W. 59th St., New York 19, Secretary.

American Orthopedic Association, The Greenbrier, White Sulphur Springs, W. Va., June 20-23. Dr. C. Leslie Mitchell, Henry Ford Hospital, Detroit 2, Secretary.

American Proctologic Society, Atlantic City, June 7-10. Dr. W. Wendell Green, 1838 Parkwood Ave., Toledo 2, Ohio, Secretary.

American Radium Society, Atlantic City, June 6-9. Dr. John Wirth, U. S. Marine Hospital, Baltimore, Secretary.

American Rheumatism Association, Hotel Dennis, Atlantic City, June 8-9. Dr. Charles Ragan, 620 W. 168th St., New York 32, Secretary.

American Society for the Study of Sterility, Ritz-Carlton Hotel, Atlantic City, June 9-10. Dr. John O. Haman, 490 Post St., San Francisco 2, Secretary.

American Therapeutic Society, Atlantic City, June 8-10. Dr. Oscar B. Hunter, 915 Nineteenth St. N.W., Washington 6, D. C., Secretary.

Association for the Study of Internal Secretions, Chalfonte-Haddon Hall, Atlantic City, June 7-9. Dr. Henry H. Turner, 1200 N. Walker St., Oklahoma City 3, Secretary.

Catholic Hospital Association of the United States and Canada, Convention Hall, Philadelphia, June 2-5. Mr. M. R. Kneifl, 1402 S. Grand Blvd., St. Louis 4, Executive Secretary.

Conference of Presidents and Other Officers of State Medical Associations, Hotel Traymore, Atlantic City, June 10. Mr. John E. Farrel, 106 Francis St., Providence 3, R. I., Secretary.

Great Falls Medical-Surgical Conference, Great Falls, Montana, June 25-26. Dr. William E. Sullens, Box 1066, Great Falls, Chairman.

Idaho State Medical Association, Sun Valley, June 17-20. Dr. Robert S. McKean, 305 Sun Building, Boise, Secretary.

Maine Medical Association, Poland Spring House, Poland Spring, June 17-19. Dr. Frederick R. Carter, 142 High St., Portland 3, Secretary.

Medical Library Association, Denver, June 28-30. Miss Caroline Riechers, Rush Medical College Library, 1758 W. Harrison St., Chicago 12, Secretary.

National Proctologic Association, Madison Hotel, Atlantic City, June 9. Dr. George E. Mueller, 1214 W. Beach Blvd., Biloxi, Miss., Executive Secretary.

Post Graduate Medical Assembly of South Texas, Shamrock Hotel, Houston, Texas, July 23-25. Mrs. W. H. Dahme, 229 Medical Arts Bldg., Houston, Executive Secretary.

Society for Investigative Dermatology, Ritz-Carlton Hotel, Atlantic City, June 7-8. Dr. Herman Beerman, 255 S. 17th St., Philadelphia, Secretary

Society for Vascular Surgery, Chalfonte-Haddon Hall, Atlantic City, June 10. Dr. George D. Lilly, 333 Ingraham Bldg., Miami 32, Fla., Secretary.

Society of Biological Psychiatry, Claridge Hotel, Atlantic City, June 17. Dr. George N. Thompson, 1136 W. Sixth St., Los Angeles 17, Secretary.

South Dakota State Medical Association, Aberdeen, June 2-6. Dr. Roland G. Mayer, 22½ S. Main St., Aberdeen, Secretary.

West Virginia State Medical Association, The Greenbrier, White Sulphur Springs, July 19-21. Mr. Charles Lively, 1031 Quarrier St., Charleston 24, Executive Secretary.

INTERNATIONAL

European Congress on Rheumatism, Barcelona, Spain, Sept. 24-27. Dr. Gunnar Edströn, Lund, Sweden, Secretary.

General Practitioners Study Club International, Rome, Italy, Sept. 12-15. Dr. John O'Connell, 10300 Lackland Road, St. Louis 14, Mo., U. S. A., President.

International Academy of Proctology, Atlantic City, N. J., U. S. A., June 7-8. Dr. Alfred J. Cantor, 43-45 Kissena Blvd., Flushing, New York, Secretary.

International Anesthesia Research Society, London, England, Sept. 3-7. Mr. R. W. Cope, University College Hospital, London W.C.1, England.

International Association of Allergists, Zurich, Switzerland, Sept. 23-29. Prof. A. S. Grumbach, Hygiene Institut der Universitaet Zurich, Gloriastr. 32, Zurich, Switzerland.

International Congress of Anesthesiology, Nursing School of the Salpiettre, 47 Boul de l'Hospital, Paris, France, Sept 20-22. 12 rue de Seine, Paris 6^{e}, France, Secretariat.

International Congress of Clinical Pathology, London, England, July 16-20. Dr. W. H. McMenemey, Maida Vale Hospital for Nervous Diseases, London W.9, England, Secretary.

International Congress of Gynecology, Maison de la Chimie, Centre Marcellin, Paris, France, June 23-29. Dr. Maurice Fabre, 1, rue Jules-Lefebvre, Paris IX, General Secretary.

International Congress on Industrial Medicine, Instituto Superior Técnico, Lisbon, Portugal, Sept. 9-15. Dr. Luis Guerreiro, Instituto Nacional do Trabalho e Previdência, Praça do Comercio, Lisbon, Secretary General.

International Congress on Mental Health, Mexico City, Mexico, Dec. 11-19.

International Congress of Military Medicine and Pharmacy, Paris, France, June 17-23. Physician General Dutrey, 8, bis, rue de Recollets, Paris X, Secretary General.

International Exhibition of Medical Arts, Turin, Italy, May 30 June 12. Prof. S. Teneff, Palazzo della Exposizioni al Valentino, Turino, Italy.

International Gerontological Congress, Hotel Jefferson, St. Louis, Mo., U. S. A., Sept. 9-14. Dr. John E. Kirk, 5600 Arsenal Street, St. Louis 9, Mo., Chairman, Program Committee.

International Hospital Congress, Brussels, Belgium, July 15-21. Capt. J. E. Stone, 10 Old Jewry, London E.C., England, Secretary.

International Poliomyelitis Congress, Copenhagen, Denmark, Sept. 3-7. Prof. Dr. Niels Bohr, Statens Seruminstitut, 80 Amager Blvd., Copenhagen S., Denmark, President.

International Society of Angiology, Claridge Hotel, Atlantic City, N. J., U. S. A., June 9. Dr. Henry Haimovici, 105 E. 90th St., New York 28, Secretary.

International Society of Surgery, Paris, France, Sept. 24-29. Dr. L. Dejardin, 141, rue Belliard, Brussels, Belgium, Secretary General.

International Society for the Welfare of Cripples, Fifth World Congress, Stockholm, Sweden, Sept. 9-14. Mr. Donald V. Wilson, 54 E. 64th St., New York 21, N. Y., U. S. A., Executive Director.

Pan Pacific Surgical Association Congress, Honolulu, Hawaii, Nov. 7-19. Dr. Forrest J. Pinkerton, Suite 7, Young Bldg., Honolulu, Hawaii, President.

Students' International Clinical Congress, Leyden, Utrecht, Groningen and Amsterdam, Holland, July 10-28. N. A. M. Bergstein, Oude Gracht 143 bis, Utrecht, Holland, Secretary General.

World Confederation for Physical Therapy, Copenhagen, Denmark, Sept. 7-8.

World Medical Association, Stockholm, Sweden, Sept. 15-21. Dr. Louis H. Bauer, 2 E. 103d St., New York 29, N. Y., U. S. A., Secretary-General.

EXAMINATIONS AND LICENSURE

NATIONAL BOARD OF MEDICAL EXAMINERS

National Board of Medical Examiners: *Parts I and II.* Various Centers, June 18-20, Sept. 5-7 (Part I only). Applications must be filed at least thirty days prior to an examination. Ex. Sec., Mr. E. S. Elwood, 225 S. 15th Street, Philadelphia.

INTERNATIONAL COLLEGE OF SURGEONS

Examinations for Certified Fellowship in the United States Chapter in Urologic Surgery, Obstetrics and Gynecology and Proctologic Surgery, Chicago, June 1-2. Examinations will be given in General and Orthopedic Surgery, Chicago, Aug. 3-4. Sec., Dr. Arnold S. Jackson, 1516 Lake Shore Drive, Chicago 10.

EXAMINING BOARDS IN SPECIALTIES

American Board of Anesthesiology: *Written.* July 20. Given simultaneously in several cities in the United States. Final date for filing application was Jan. 20. *Oral.* Memphis, Oct. 14-17. *Written.* July 18, 1952, Various locations. Final date for filing applications is Jan. 18, 1952. Sec., Dr. Curtiss B. Hickcox, 80 Seymour St., Hartford 15, Conn.

American Board of Dermatology and Syphilology: *Oral.* New York, June 8-10. Sec., Dr. George M. Lewis, 66 East 66th St., New York 21, N. Y.

American Board of Internal Medicine: *Written.* Various centers, Oct. 15. *Final date for filing* applications was May 1. *Oral.* The schedule of oral examinations for 1951 has been arranged on a regional basis as follows: June, includes candidates from Beirut, Canada, Canal Zone, Connecticut, Delaware, District of Columbia, Maryland, New Jersey, Ohio, Pennsylvania, Puerto Rico, Rhode Island, Virginia and West Virginia. Public Health Service; formerly affiliated with Veterans Administration Hospital in Bay Pines, Fla.; served during World Wars I and II; died March 15, aged 59, of amyotrophic lateral sclerosis.

Herrington, L. C., Terry, Miss.; Memphis Hospital Medical College, 1904; member of the American Medical Association; died in Baptist Hospital, Jackson, March 18, aged 70, of retroperitoneal adenocarcinoma.

Kerns, Francis John ⊕ Newark, N J.; Georgetown University School of Medicine, Washington, D. C., 1903; past president of the Pathological Society of New Jersey; affiliated with St. Mary's Hospital in Orange and St. Michael's Hospital and Presbyterian Hospital, where he died March 23, aged 71, of cerebral thrombosis.

Knapp, John Christian ⊕ Setauket, N. Y.; Albany (N. Y.) Medical College, 1916; specialist certified by the American Board of Radiology; member of the American College of Radiology; for many years affiliated with St. John's Hospital in Brooklyn; on the staff of Mather Memorial Hospital in Port Jefferson; served overseas during World War I; died March 15, aged 57.

Langston, John Earl, Houston, Texas; Baylor University College of Medicine, Dallas, 1916; member of the American Medical Association, died in March, aged 62, of suffocation and burns.

Lawson, Claudius Simuel, Fairmont, W. Va.; Medical College of Virginia, Richmond, 1910; member of the American Medical Association; died March 22, aged 71, of injuries suffered in an automobile accident.

Ledbetter, Franklin Carver, Greenville, S. C.; Southern College of Medicine and Surgery, Atlanta, 1914; member of the American Medical Association; died March 2, aged 61, of acute coronary occlusion.

Leonard, Bertram Bryant Jr., Yankton, S. D.; State University of Iowa College of Medicine, Iowa City, 1927; member of the American Medical Association; affiliated with Sacred Heart Hospital; died March 28, aged 49, of heart disease.

Long, Merrill Harrison ⊕ Altoona, Pa.; Hahnemann Medical College and Hospital of Philadelphia, 1921; affiliated with Altoona and Mercy hospitals; died March 18, aged 53, of diabetes mellitus and pneumonia.

Lowe, William Cook, Queenstown, Md.; University of Maryland School of Medicine and College of Physicians and Surgeons, Baltimore, 1941; served during World War II; died February 3, aged 33.

Lyda, Edwin Earle, San Bernardino, Calif.; St. Louis University School of Medicine, 1941; member of the American Medical Association; affiliated with St. Bernardino's Hospital, where he died March 15, aged 37, of bronchopneumonia, cerebral infarcts, bacterial endocarditis and thrombophlebitis.

McAdams, Edward Calvin ⊕ Wilkinsburg, Pa.; University of Pittsburgh School of Medicine, 1909; served as a visiting physician at Columbia and Western Pennsylvania hospitals and on the staff of St. Joseph's Hospital; died March 12, aged 67, of uremia.

McCandless, Oliver Howard, Independence, Mo.; University Medical College of Kansas City, 1901; specialist certified by the American Board of Radiology; member of the Radiological Society of North America, American Medical Association, and the American College of Radiology; served on the staff of the Independence Sanitarium and Hospital, where he died May 2, aged 75, of carcinoma of the stomach.

McClure, John B., Marietta, Ohio; Medical College of Ohio, Cincinnati, 1896; for many years health commissioner; coroner; affiliated with Marietta Memorial Hospital, where he died March 30, aged 79, of cerebral thrombosis.

McDermott, William Carlton, Peoria, Ill.; Chicago Medical School, 1940; member of the American Medical Association; clinician to the city health department; affiliated with St. Francis Hospital, where he died March 27, aged 40, of uremia, rheumatic heart disease, and pneumonia.

McLandress, Joshua Alexander ⊕ Saginaw, Mich.; Saginaw Valley Medical College, 1902; affiliated with St. Luke's Hospital, St. Mary's Hospital, and the Saginaw General Hospital, where he died March 20, aged 73, of cerebral thrombosis.

McLean, Ray Allyn, Fayette, Iowa; State University of Iowa College of Medicine, Iowa City, 1906; died March 27, aged 73, of heart disease.

McMechen, Harry B., Hannibal, Mo.; Meharry Medical College, Nashville, Tenn., 1911; died April 3, aged 64, of coronary thrombosis.

McSorley, Frederick William, New York; Albany (N. Y.) Medical College, 1909; served during World War I; retired assistant medical director of the Equitable Life Assurance Society of the United States; died March 24, aged 67, of heart disease.

Maker, Louis Edward, Fort Collins, Colo.; Drake University Medical Department, Des Moines, Iowa, 1897; died February 1, aged 77, of cerebral hemorrhage.

Mallow, Edgar H., Columbus, Ohio; Medical College of Ohio, Cincinnati, 1900; died March 24, aged 76, of heart disease.

Mann, Sigmund, Oak Park, Ill.; Chicago College of Medicine and Surgery, 1916; died in the Albert Merritt Billings Hospital, Chicago, April 16, aged 65, of hemorrhagic infarction of the lung.

Mathis, James Edgar, Burns, Tenn.; University of Tennessee Medical Department, Nashville, 1889; died February 3, aged 84, of cerebral hemorrhage.

Miles, Bertram James, Wilkinsburg, Pa.; University of Pittsburgh School of Medicine, 1934; member of the American Medical Association and the American Association of Industrial Physicians and Surgeons; associate surgeon, Columbia Hospital; died March 15, aged 41, of cerebral hemorrhage.

Moore, George Washington, Cincinnati; Cincinnati College of Medicine and Surgery, 1895; died March 14, aged 82, of congestive heart failure and pulmonary edema.

Myers, Henry Dey Sr. ⊕ Howells, Neb.; Drake University College of Medicine, Des Moines, 1906; chairman of the board of health and for many years member of the school board of Howells; died April 3, aged 72, of cerebro-vascular accident.

Payne, John Lewis, Cincinnati; Eclectic Medical College, 1899; formerly on the faculty of his alma mater; died in St. Francis Hospital March 12, aged 77, of cerebral hemorrhage.

Peters, Melvin Lester, Cameron, Mo.; University Medical College of Kansas City, 1905; served two terms as mayor of Cameron; died March 4, aged 78, of cerebral hemorrhage.

Petrik, Albert Charles, Fairhope, Ala.; University of Illinois College of Medicine, Chicago, 1930; member of the American Medical Association; served during World Wars I and II; died in the Veterans Administration Hospital, Montgomery, February 24, aged 55, of cerebral hemorrhage and hypertensive cardiovascular disease.

Pfletschinger, Frederic, New York; Columbia University College of Physicians and Surgeons, New York, 1902; member of the American Medical Association; affiliated with Lutheran Hospital, where he died March 18, aged 71, of arteriosclerotic heart disease.

Pinner, Oskar, Livermore, Calif.; Albertus-Universität Medizinische Fakultät, Königsberg, Prussia, Germany, 1911; affiliated with Veterans Administration Hospital; died in Alta Bates Hospital, Berkeley, March 4, aged 66, of carcinoma.

Prince, Norman Call ⊕ Amarillo, Texas; Denver and Gross College of Medicine, 1907; specialist certified by the American Board of Radiology; member of the Radiological Society of North America and the American College of Radiology; died February 23, aged 66.

Pyles, John Wylie ⊕ New Martinsville, W. Va.; Jefferson Medical College of Philadelphia, 1926; member of the state legislature, 1937-1938; died in the Ohio Valley General Hospital, Wheeling, March 15, aged 50, of bronchopneumonia.

Radcliff, Ernest, Jonesboro, Ill.; Washington University School of Medicine, St. Louis, 1906; member of the American Medical Association; died March 17, aged 74.

Rainone, Michele, Brooklyn; St. Louis University School of Medicine, 1932; member of the American Medical Association; honorary lieutenant of the New York Police Department; for many years on the staff of the Swedish Hospital, died February 3, aged 48, of heart disease.

Rawlins, Elbert Van der Heyden, Roodhouse, Ill.; St. Louis University School of Medicine, 1904; died January 27, aged 76.

Razinsky, Louis ⊕ Warren, Ohio; University and Bellevue Hospital Medical College, New York, 1931; specialist certified by the American Board of Internal Medicine; served in the European theater during World War II; affiliated with St. Josephs Riverside Hospital, where he died March 9, aged 44, of coronary thrombosis.

Reynolds, Clifton Johnson, Bluefield, W. Va.; University of Virginia Department of Medicine, Charlottesville, 1920; specialist certified by the American Board of Urology; member of the American Medical Association and American Urological Association; fellow of the American College of Surgeons; president of the section on urology of the West Virginia State Medical Association; affiliated with Bluefield Sanitarium; died March 24, aged 54, of heart disease.

Richards, Robert Milton, Detroit; Cleveland Medical College, Homeopathic, 1894; served on the staffs of the Grace and Harper hospitals; for many years house physician for the Statler Hotel; died March 17, aged 82, of coronary thrombosis.

Robbins, Charles Mortimer ⊕ Newark, N. J.; University and Bellevue Hospital Medical College, New York, 1914; specialist certified by the American Board of Surgery; fellow of the International College of Surgeons and the American College of Surgeons; past president of the Academy of Medicine of Northern New Jersey; served during World War II; affiliated with Beth Israel, Presbyterian, and Irvington General hospitals; died April 4, aged 61.

Rodholm, Ansgar Kolhede ⊕ Corpus Christi, Texas; University of Chicago School of Medicine, 1938; specialist certified by the American Board of Orthopaedic Surgery; served during World War II; affiliated with Spohn, Memorial, Ghormley Clinic, and Crippled Children's hospitals; died March 20, aged 44, of injuries received in an automobile accident.

Rozanski, Frank Stanley, Worcester, Mass.; Hahnemann Medical College and Hospital of Philadelphia, 1937; member of the American Medical Association; public school physician; served during World War II; on the courtesy staffs of St. Vincent and Fairlawn hospitals and the Hahnemann Hospital, where he died March 5, aged 37, of ruptured esophageal varices and cirrhosis of the liver.

Sage, Arthur Gray ⊕ Buffalo; New York University Medical College, New York, 1898; on the staff of the Sisters of Charity and Deaconess hospitals; died March 30, aged 81, of coronary thrombosis.

Swann, Joseph Charles, Wedowee, Ala.; Atlanta Medical College, 1890; died February 20, aged 81, of hypostatic pneumonia, arteriosclerosis, and hypertension.

Tatum, William Jefferson, Richland, Ga.; Southern Medical College, Atlanta, 1896; died February 4, aged 78.

Thompson, Frederick E., Columbus, Ohio; Columbus Medical College, 1888; formerly practiced in Marengo, where he was a member of the Morrow County Board of Health; died March 24, aged 85.

GOVERNMENT SERVICES

DEPARTMENT OF DEFENSE

CREDIT FOR ATTENDANCE AT SESSIONS ON MILITARY MEDICINE AT ATLANTIC CITY SESSION

We have been informed that each medical officer who attends the Sessions on Military Medicine in the Section on Miscellaneous Topics at the Atlantic City Session and registers at the entrance to the Rennaisance Room of the Ambassador Hotel will receive one credit point for attendance at each of the half-day sessions. In other words, if such officer attends both meetings of the Sessions on Military Medicine, he will receive two credit points. If he attends only one, he will receive only one credit point.

PUBLIC HEALTH SERVICE

Industry Needs More Water.—The need of industry for greater supplies of usable water to meet the nation's defense production schedules was emphasized in discussions before the water pollution control advisory board of the Public Health Service, Federal Security Agency, in Washington, D. C., April 18 and 19. During the two-day session the board heard reports on the progress of the cooperative work by the states and the Public Health Service for development of comprehensive water pollution control programs, and on other activities in government and private fields bearing on the pollution problem. The board discussed prospects for sewage and industrial waste treatment plant construction. Arrangements are being made to take care of needs for water supply and sewage disposal plants pending designation of a claimant agency of the government for these functions.

The increased supply of water required by industry to fill defense orders was emphasized by a member of the board. The efforts of industry to increase its supplies of usable water by controlling pollution were described. Industry in the Philadelphia area is spending 25 million dollars to fight pollution, and individual companies are investing millions of dollars a year for treatment works and for research to prevent pollution by improving their "housekeeping practices."

In a review of the work of the President's Water Resources Policy Commission the seriousness of the situation was emphasized.

Laboratory and Field Training Courses.—One hundred and one laboratory and field training courses are being offered this year by the Public Health Service. All courses emphasize training personnel to maintain health services in defense and mobilization. The majority of courses are being conducted by the Communicable Disease Center, Atlanta, Ga. Ten courses will be given by the Environmental Health Center, Cincinnati. The training is primarily for employees of state and local health departments, but employees of nonprofit institutions are eligible. Over 450 foreign public health workers from 70 countries have attended these courses since the end of World War II.

Refresher courses in the principles and practice of laboratory methods for the diagnosis of disease are conducted in Atlanta and Chamblee, Ga., and in Montgomery, Ala. Field training courses in the environmental aspects of disease control are conducted under a cooperative federal-state program to develop more effective field training for all types of public health workers. These courses are held in Atlanta and also at regional training centers located in Amherst, Mass.; Buffalo; Pittsburgh; Bloomington, Ill.; Columbus, Ga.; Topeka, Kan., and Denver. Applicants must be approved by their state health officer. Additional information about the training may be obtained from the Communicable Disease Center.

Training in radiological health, water pollution abatement and milk and food sanitation is conducted by the Environmental Health Center. State and local health department employees should apply for training through their state health officer. Others should apply through the sponsoring agency. Additional information may be obtained from the Training Section, Environmental Health Center, 1014 Broadway, Cincinnati 2.

Training at Communicable Disease Center.—A group of 35 Public Health Service officers are at the Communicable Disease Center, Atlanta, for a month's special training before assignment to the Economic Cooperation Administration to staff public health projects of the special technical and economic mission in southeast Asia. Their training in Georgia will include malaria control, other insect-borne disease control, and rural sanitation. The group, all commissioned officers in the Public Health Service, includes physicians, entomologists, malariologists, nurses, sanitary engineers, sanitarians, and health educators.

Navy and army personnel currently are being trained at the Communicable Disease Center in milk and food sanitation, inspection and sanitary practices in eating places, water pollution control, emergency repair and establishment of water supplies, sewage and garbage disposal, and camp sanitation. In addition, insect and rodent training emphasizes the control of mosquitoes, flies, rodents, and other disease-carriers.

Twelve-week courses in these subjects have been given by CDC, in cooperation with navy instructors, at Annapolis, Md., for navy petty officers and state of Maryland sanitarians. Four-week courses covering the same fields have been given by CDC at Atlanta and Columbus, Ga., for selected army personnel attached to preventive medicine units. Similar training has been given for years by the Communicable Disease Center for its own and state and local health department personnel.

Study of Toxic Residues on Foods.—A western toxicology laboratory is being established jointly by the Communicable Disease Center of the Public Health Service and the State College of Washington's experiment station. The laboratory will be in Wenatchee, Wash., and its staff will include a medical officer, a biologist, and a chemist, as well as other personnel. The new research project was initiated to determine the public health hazards of toxic residues on foods. Little is known, it is pointed out, about the toxicity to humans of residues from the new poisons that have proved so effective in the control of insect pests. The purpose of the investigation is to determine if any injury results from the absorption of such residues over a long period of time. The first study to be made by the new laboratory will be an investigation of the hazards associated with the use of parathion and dichlorodiphenyltrichloroethane (DDT) in apple orchards, as well as the effects of other insecticidal sprays on fruits and vegetables.

Japanese Health Workers in Training.—Thirteen physicians and other health workers from Tokyo, Japan, have arrived in the United States for three months of training under programs supervised by the Division of International Health of the Public Health Service. The training is being conducted under a fellowship program arranged by the Military Government of Japan. Among the trainees are:

Dr. Kiyoshi Ando, chief of the First Bacteria Division, National Institute Health, who will study manufacture and assay of biologics production, especially toxin and antitoxin.

Dr. Junjiro Okanishi, director of the Koichikawa Health Center, who will review communicable disease control in small towns.

Dr. Takehisa Omura, chief of the National Sanatoria Section, Ministry of Welfare, who will study operation of tuberculosis sanatoriums.

Dr. Ken Yanagisawa, Chief of the Tuberculosis Division, National Institute of Health, who will review American tuberculosis control and research programs.

PARIS

Cortisone and Gestation.—Several years ago, Prof. Robert Courrier, general secretary to the Academy of Sciences, studied the influence of desoxycorticosterone on the gestation of rabbits. He found that this substance can replace the corpus luteum hormone; it allows the evolution of pregnancy in the castrated pregnant animal. Recently, in collaboration with Mme. Andrée Collonge, Professor Courrier studied the effect of cortisone on gestation. Rabbits were given daily injections of 25 mg. of cortisone acetate, dissolved in 1 cc. of an excipient, during four to seven days, between the 10th and the 23d days of gestation. This experiment gave the following results: Some rabbits aborted; with separation of the placenta; in others a hemorrhage occurred. When injections were given between the 10th and 14th days of pregnancy, autopsy revealed, besides living fetuses, evidences of resorbed ones; fetuses were diminished in size, from 24 to 20 mm., and placentas were pale. When injections were given between the 15th and the 21st days, all fetuses were found macerated, 15 to 38 mm. in size instead of 54 mm. (normal size), and ovarian yellow bodies were small and pale. The authors presented these results to the Academy of Sciences, March 19, 1951, and concluded by stating that cortisone has a deleterious effect on the gestation of rabbits, especially if injected after the 15th day of pregnancy.

Vitamin B_{12}.—P. L. Drouet, Wolff, Mme. Karlin and G. Rauber presented the results of their researches on vitamin B_{12} levels in human and animal liver "in vivo" to the Medical Society of the Paris Hospitals at the meeting of March 2, 1951. First, the authors studied these levels in the ox and found that they range from 0.5 to 1.5 gamma per gram of liver parenchyma. Having then taken samples from human corpses, they noted a level of 0.5 to 0.7 gamma per gram of body tissue. In six patients with multiple sclerosis, tuberculosis, chronic ethylism or hemolytic icterus, levels varied from 0.478 to 1.14 gamma. All these studies were made on fragments of hepatic tissue weighing 5 to 32 mg. and taken by biopsy puncture. This measurement of vitamin B_{12} levels was effected by a microbiologic process, with the use of a micro-organism (Lactobacillus) that requires for its growth the presence of vitamin B_{12} in the culture. By comparing the growth of organisms with that obtained in mediums containing a titrated solution of crystallized vitamin B_{12}, one can assess the vitamin B_{12} content of liver fragments. After these preliminary studies, which the authors described at a recent meeting of the Academy of Sciences, they studied the vitamin B_{12} hepatic levels in patients with pernicious anemia before and after treatment. In five patients, before treatment, a considerable fall of the hepatic vitamin B_{12} levels (0.023, 0.037, 0.041, 0.071, and 0.14 gamma) was noted; after treatment with an hepatic extract or vitamin B_{12} (30 to 50 gamma per day), there occurred a considerable rise in the hepatic vitamin B_{12} levels (0.068, 0.198, 0.17, 0.166, and 0.272 gamma); these levels were then two and even five times higher than previously. These first results of the researches give for the first time direct evidence in vivo of the role of liver in the physiopathology of pernicious anemia and also suggest research on other vitamins.

International Youth Center.—The official opening of this center, dedicated to "the first year of life," will take place April 19-July 15, 1951. The exhibit will cover (1) infantile mortality; historic evolution and present condition in various countries; mortality according to age and causes, especially during the first months of life; (2) various dangers threatening infants; (3) rachitism and premature weaning; (4) lack of maternal care; (5) sanitary and social protection of youth, and maternal and infantile protection, and (6) normal growth of infants. Conferences and movies will be included. Later, this exhibit will be presented in several large cities of France and foreign countries. The international center intends to organize other exhibits on other subjects relating to youth.

Death of Professor Jacques Roubinovich.—J. Roubinovich, well-known French psychiatrist, died at the age of 88. He was chief of the children's ward at Bicêtre, having succeeded his master, Bourinville. His scientific works are numerous and cover various fields, such as alienation, progressive psychosis, melancholia, dementia precox, general paralysis, epilepsy, idiotism and tics. In all his work, he endeavored to discover the relations between psychic diseases and organic syndromes. He was vice president of the league for mental hygiene. He was also interested in juvenile delinquency, and, with Professor Heuyer, he advocated that juvenile offenders be routinely subjected to a medicopsychologic examination. Roubinovich had a strong personality, which he showed during the occupation of Paris by the Nazis. Arrested by them at the age of 80 and interned at the Rothschild Hospital, he sustained the courage of his companions.

ITALY

Cancer of the Rectum and Its Surgical Therapy.—In discussing the paper by Professor Bastianelli at the National Congress of Surgery (*J. A. M. A.* 146:56 [May 5] 1951) Professor Paolucci, of Rome, reported on about 100 cases of cancer of the rectum treated by him in the past 12 years. Thirty-six of these underwent palliative intervention, while radical surgical intervention was performed in 70 patients. In 1932, at a meeting of Italian surgeons convened to discuss late results of surgery of cancer of the rectum, Professor Paolucci reported on about 30 surgically treated patients. Almost all the patients operated on by perineal approach had died from metastasis or local recurrence of the tumor. Of the patients operated on by abdominoperineal approach, a good percentage survived. He then became convinced that the only truly radical operation giving lasting satisfactory results was abdominoperineal intervention.

Paolucci concluded that the cause of the recurrences was the one stressed by Professor Bastianelli in his report, that the opening of the fascia propria of the rectum actually causes the spread of the tumor. Professor Paolucci admitted, also, that until some time ago he did not care to save the sphincter in those interventions, because he believed that the intervention should be as radical as possible or because the operation may be prolonged when the sphincter is preserved. He now concludes that the sphincter itself should be spared whenever possible.

Professor Ceccarelli, of Padua, stressed the great value of Professor Bastianelli's report, which included the results of his wide experience as a distinguished surgeon. Professor Ceccarelli's own cases of cancer of the rectum are limited to 51, in 17 of which resection was done by perineal approach and in 18 by the abdominoperineal route (Miles technique), while 15 patients were operated on by abdominoperineal approach with preservation of the sphincter, according to Bastianelli's technique. The speaker emphasized the importance of preoperative treatment. He performed resection in 39 cases, in which colostomy was well tolerated; two patients refused to undergo operation, not wishing to have an artificial anus. In 15 cases operated on with preservation of the sphincter, according to the method widely used by Bastianelli, the regular function of the intestine was preserved, which is of capital importance.

Professor Dogliotti, of Turin, stressed some fundamental points and reported on his present surgical procedures, different than those he followed in former years. In general, he is in favor of saving the sphincter in cases of cancer located in the upper part of the ampulla of the rectum and in cancer of the rectosigmoid. Lately, he performs an end to end anastomosis in suitable cases.

The abdominoperineal intervention of Miles gives satisfactory results for cancer of the ampulla. For low located cancer, he previously preferred resection by perineal approach with an artificial anus in the sacral region, but now he is inclined to use the abdominoperineal approach even in these cases.

The preoperative preparation of the patient is of greatest importance. It consists of administration of fluids and isotonic

---

The items in these letters are contributed by regular correspondents in the various foreign countries.

sodium chloride solution, blood transfusion and vitamins, evacuation of the intestines and use of antibiotics. Good nutrition of the loop undergoing anastomosis is also of particular importance, as well as the selection of an area in which pulsations of the arterioles may be clearly observed.

Interrupted sutures should be made with silk, in three layers; antibiotic powder should be dusted between the layers and on the exterior surface. The operative death rate registered was very small.

Oral Administration of Streptomycin.—At the Medico-Surgical Society of the Romagna, presided over by Professor De Castro, Professor Jasonni presented a report on the oral use of streptomycin in some infections of the intestine and of the biliary tract. He discussed the present knowledge of oral administration of this antibiotic, its insufficient absorption by this route, and the high concentration of streptomycin in intestinal excretion. It is possible to use streptomycin by oral route in some intestinal infections caused by very sensitive germs, and favorable results have been reported in acute gastroenterocolitis of infants and young children caused by Bacterium coli, Proteus vulgaris, Salmonella and other gram-negative organisms. More doubtful are the data on salmonellosis in adults, in which condition streptomycin is given orally by surgeons especially before operation on the large intestine, in order to eliminate the coli bacilli from the feces. In typhoid and paratyphoid, the effects were not very definite and are not comparable to those obtained with chloramphenicol.

After these preliminaries, based on a survey of the literature, Professor Jasonni reported the results obtained in his own cases. In enteritis of children, even when severe and refractory to other methods of treatment, oral streptomycin therapy proved definitely beneficial. Tolerance of adequate doses also has been gratifying in small children. In cases of acute enterocolitis of adults, accompanied sometimes by alarming gastrointestinal manifestations and by severe general repercussions, highly satisfactory results were obtained with oral administration of streptomycin. Streptomycin has been administered orally as an adjuvant to chloramphenicol therapy in seven cases of typhoid; seven recoveries were reported without recurrence, accompanied by a particularly rapid sterilization of the feces.

The results obtained by oral administration of streptomycin in some cases of infectious jaundice due to ascending angiocholitis are also interesting. Because of these favorable observations, the speaker proposes to try oral administration of streptomycin in ascending cholangitis due to micro-organisms especially sensitive to the antibiotic.

NORWAY

Care of the Aged.—The Norwegian National Association Against Tuberculosis and for Health was originally founded only for combating tuberculosis. The latter part of its present title is a comparatively late addition and is an indication that this rich and influential body has greater ambitions than fighting tuberculosis. One of the most recent digressions from tuberculosis is the welfare of the aged, for whom health control stations and consultative stations are soon to be established. The association is also prepared to stimulate and support scientific investigations concerning the health problems of the aged. It has also recently issued a pamphlet on the health of the aged, in which Dr. Per Hanssen outlines the principles to be followed. The municipal authorities in Oslo are now engaged on the provision of a new infirmary for the aged with some 400 beds in connection with the large Ullevaal city hospital. This infirmary will, it is hoped, be available for use in 1952. However, there will remain a need for some 800 more such beds for the aged. The Oslo medical society is taking an active part in welfare schemes for the aged; it recently organized a meeting at which the subject was discussed from various angles. If the age distribution of the population of the whole of Norway conforms to the calculations of the statisticians, the country will in 1975 have some 150,000 more pensioners and persons unfit for work than it has at the present time.

Paintings in Hospital Wards.—A small storm occurred recently when some doctors in Bergen declined an offer of paintings to be hung in their respective hospitals. Prof. Gabriel Langfeldt, who is in charge of the university psychiatric clinic in Oslo, circulated a questionnaire among his patients, who were given no time in which to consult each other and influence each other in the answers they gave. They were asked: 1. Do you like the pictures on the walls? 2. What effect do they have on you? Do they soothe you, cheer you, depress you, have no effect on you or are they repugnant to you? 3. Would you like some of the pictures to be removed? 4. If so, which? The answers to these questions showed that 62% of the patients liked the pictures and 25% did not like them, while 13% both liked and disliked them. The pictures had a soothing or cheering effect on 57%, no particular effect on 24% and a depressing or repugnant effect on 19%. The wish that all the pictures be removed was expressed by 16%, that none of them should be removed by 71% and that some of them should be removed by 13%.

It will thus be seen that most of these resident hospital patients approved of the pictures on their walls, finding them beneficial. But it was remarkable that, in as high a proportion as 19%, dislike of the pictures was expressed. These pictures were colored lithographs of modern painters, some of whose works were subjected to devastating criticism. Professor Langfeldt's reaction to this poll is to admit that there was some justification for the attitude of the hospital doctors in Bergen. He has decided to remove from the wards to the corridors of his hospital those pictures to which some of his patients objected. In their place he will hang peaceful landscapes and the like.

Better Remuneration for Junior Hospital Appointments.—Hitherto the pay of junior medical officers in hospital has been very meager. The hospital authorities recently have had to reconsider the situation in the light of a shortage of doctors, the younger generation of doctors having formed the Association of Junior Doctors, with Dr. Kaare Schanke as its chairman. A year ago the lowest paid intern received kr. 7,825, a senior intern kr. 9,825, and the chief's second in command, "the reserve doctor," kr. 11,825. The scale of remuneration was practically the same whether the hospitals belonged to a municipality or the state. The interns in the state hospitals had a pension scheme to which contribution was taken out of their salaries.

The Association of Junior Doctors is affiliated with the senior body, the Norwegian Medical Association, and is in a fairly strong position to bargain for its members. Negotiations last August between it and certain municipal authorities led to a stalemate. The doctors did not strike outright, but they did not apply for vacancies when they occurred on the old scale of remuneration. With the supply of new junior medical officers thus effectively cut off, it became obvious during last autumn that the position would be quite untenable for the hospitals at the beginning of 1951. Resumed negotiations led to a salary for the lowest paid intern of kr. 11,156 and a corresponding rise for the senior appointments.

Compulsory BCG Vaccination.—When, in 1947, the Norwegian parliament made BCG vaccination compulsory, the public health authorities in many other countries must have wondered whether this bold pioneer step would be successful. At a recent meeting of the Norwegian Medical Tuberculosis Society, Dr. S. Garegg of the tuberculosis department of the Oslo public health service quoted some figures which throw light on this subject. He was dealing with medical examinations of persons employed in industry. Altogether, 32,982 persons employed by 399 industrial concerns were subjected to mass radiography and tuberculin testing in 1949. In 81.7% a positive tuberculin reaction and in 18.3% a negative tuberculin reaction was observed. As great a proportion as 83.3% of the negative reactors consented to BCG vaccination. This percentage was only 42.5 in 1945, only 44.1 in 1946 and only 36.4 in 1947, the year in which BCG vaccination was made compulsory. The pressure put on negative reactors to accept BCG vaccination is of the persuasive order, and it may well be that many accept such vaccination not because they are forced against their will but because the fact of its being compulsory convinces them of its intrinsic merits. The figures just quoted may not necessarily be proof of the success of legislative compulsion, but they are at any rate suggestive of it.

CORRESPONDENCE

EVALUATION OF NEW DRUGS

To the Editor:—It is pertinent to keep the published record clear regarding the standards and ideals of scientists and physicians of the United States. Especially is this necessary in matters involving new and allegedly useful methods of handling disease. Distressing, therefore, is the spectacle of reputable scientific medical men promoting persuasive but dubious arguments and evidence on a material for use in cancer which has suspicious commercial association and on which satisfactory chemical analysis or pharmacological appraisal has not yet been issued in customary scientific or medical publications.

Those who would like to know what technical procedures are available for the reasonably satisfactory introduction of new therapeutic agents may refer to the following publications: "The Pharmacologic Evaluation of New Drugs" (*J. A. M. A.* **93**:1632 [Nov. 23] 1929); "Laboratory and Clinical Appraisal of New Drugs" (*J. A. M. A.* **126**:958 [Dec. 9] 1944); "Current Pharmacology: General Principles and Practical Clinical Application" (*J. A. M. A.* **138**:730 [Nov. 6] 1948), and the current issue of "New and Nonofficial Remedies."

It is a source of wonderment that respected scientific medical men interested in developing new therapeutic agents should neglect the suggestions offered in these publications.

Chauncey D. Leake, Ph.D.,
Vice President,
University of Texas, for the
Medical Branch, Galveston.

MULTIPHASIC SCREENING

To the Editor:—I feel reasonably certain that Dr. Wilson G. Smillie would be greatly disappointed if nobody were to take issue with some of the thoughts expressed in his provocative article in the April 21, 1951, issue of The Journal. In my opinion, Dr. Smillie does an excellent job of presenting the pro's and con's of multiphasic screening, but the conclusions he reaches do not seem to follow logically from the premises he establishes. Any procedure which is relatively inexpensive and which will bring to light "27 to 47 cases of previously undetected serious pathological conditions" in every 1,000 persons examined, and a considerably larger number of less serious abnormalities, can hardly be characterized as "unsound in its concepts, untenable in its principles and indefensible in its logic."

If, as Dr. Smillie asserts, it is "a complete wastage of time and effort" to include chest x-ray examinations of school children in a screening survey, there is no reason why this particular procedure *cannot be omitted*, and the same can be said for cancer detection tests in persons under 35 years of age. All syphilologists do not share Dr. Smillie's lack of interest in serological tests in persons over 40 years of age.

One would hardly disagree with Dr. Smillie that it would be preferable for an *individual* to "see his physician first and . . . be referred by his physician to the health center for the various diagnostic aids." The simple fact is, as Dr. Smillie surely knows, that people do not go to their physicians for preventive services even when they have physicians to go to. Up until the time of the introduction of the "scare" influence of cancer detection examinations and the subsequent development of multiphasic screening programs, all efforts to have people submit to periodic or preventive examinations were a dismal failure. It seems to me that the important consideration is to find incipient disease through any practicable procedure and that the utilization of multiphasic techniques does not necessarily exclude private physicians from making what contributions they can to case finding and early diagnosis.

I agree with Dr. Smillie that it is important to avoid imparting a false sense of security to persons in whom no abnormalities are detected in a screening examination. It should be a simple matter to accomplish this through proper wording of the report.

Dr. Smillie very properly makes a plea for adequate medical care for everyone. Up to the present time, no completely satisfactory method of accomplishing this has been found, although great strides are being made. Until we arrive at the millenium, we should take full advantage of those measures that are available and practicable, even though they may not be perfect.

MISCELLANY

STATEMENT ON ANTIHISTAMINICS

By Committee on Public Health Relations of The New York Academy of Medicine

The Committee on Public Health Relations of The New York Academy of Medicine is concerned over the continued emphasis on the use of antihistaminic drugs for the prevention and treatment of the common cold. These drugs have been used successfully for several years by the medical profession for the treatment of allergic states. Studies of the common cold have shown that it is not due to a single cause. "Colds" may be caused by a variety of organisms and conditions. The symptoms vary with the cause, the season, the person's susceptibility, and many other factors. If these symptoms are caused by allergy, the antihistaminic drugs may give relief, but no known effect on a virus or bacterial invasion has yet been demonstrated. In evaluating reports that the antihistaminic drugs have stopped colds when taken within the first hour, it should be borne in mind that it is extremely difficult to judge within such a short time whether one actually has a cold. Again, colds may be so slight that they vanish within twenty-four or forty-eight hours without treatment. As a matter of fact, many persons who have been given placebos, or inert substances, instead of the antihistaminics have frequently done as well as those treated with the drugs, and sometimes even better.

The use of antihistaminic drugs is not without hazards. In some persons troublesome reactions occur. Fortunately, most of the reactions are mild; they may, however, have serious results. For example, the drugs may induce drowsiness or dizziness which may lead to accidents, particularly among drivers of automobiles, pilots of aircraft or operators of machinery, in whom efficiency and judgment may be temporarily impaired.

Severe reactions are not common, but they do occur, and their mechanism is not yet well understood. Children appear to be more susceptible to the drugs than adults, and are more subject to convulsions. Eight infants under two years of age are reported to have died from the effects of antihistamines, and several others are reported to have had convulsions. Most of these cases resulted from accidental overdosage. The ill effects of the antihistamines are most frequently exerted on the nervous system, but they have been known to affect the heart and the digestive tract, and there have been a few instances in which granulocytopenia, a serious disease in which the white blood cells are diminished, has been traced to these agents.

Packages of antihistaminic drugs sold to the public carry directions for dosage, but this is not sufficient protection against accidental overdosage or other hazardous use, especially in children. Allergists have estimated that at least 20 per cent of the people who take antihistamines in the doses recommended will experience undesirable if not dangerous reactions. Several persons are reported to have attempted suicide by taking excessive doses of antihistaminic drugs, and one succeeded.

Another hazard of the antihistaminic drugs as a cure for colds is that what may appear to be a "cold" is really the beginning of a serious infection and this may be neglected while the sick person is taking antihistamines on his own responsibility.

There have been cases of pneumonia in which antihistamines have been taken for several days before the real nature of the disease was discovered, and in this way valuable time for proper treatment of the disease has been lost.

It is the opinion of the Committee on Public Health Relations of The New York Academy of Medicine that the antihistaminic preparations are of no value in the treatment of true colds and that the public should be warned of the hazards attending their use.

MEDICAL MOTION PICTURES

The Migraine Headache: 16 mm., color, sound, showing time 22 minutes. Prepared by A. P. Friedman, M.D., Director, Headache Clinic, Montefiore Hospital, New York; Associate Professor, Neurology, College of Physicians and Surgeons; Regional Consultant, Veterans Administration. Produced in 1950 by Sturgis-Grant Productions, 314 East 46th St., New York 17. Procurable on loan from Sandoz Pharmaceuticals Inc., 552 West Lake St., Chicago 6.

This motion picture follows one patient from early childhood through to the present time, when she is about 22 years of age. Emphasis is placed on the various tests employed in the proper diagnosis of her vascular headache, such as the taking of a complete case history and physical and neurological examination. The method of treatment for aborting the acute attack with vasoconstrictors is also shown.

The film presents a somewhat distorted discussion of the etiology of migraine, since it leans so heavily on the psychosomatic aspects of the syndrome. Thus, the endocrine and allergic theories are given cavalier treatment, the eye is disregarded and the relation with epilepsy is ignored. Excellent animated sequences of the pathologic physiology of migraine are marred by the failure of the narration to deal with the vasoconstriction phase in any detail. The percentage of relief cited in the discussion of therapy is high and is the experience of a single investigator; this should be made clear or verified by other authority.

The use of both black and white and color film in this picture is not good technic, and the abstract sequence which illustrates an unstable personality is very confusing. Otherwise the photography, animation and narration are well done.

Feelings of Depression: No. 4 of Mental Mechanisms Series. 16 mm., black and white, sound, showing time 29 minutes. Prepared with the technical advice of the medical staff of the Allan Memorial Institute of Psychiatry, McGill University and the Royal Victoria Hospital, Montreal. Produced in 1950 by the National Film Board of Canada for the Mental Health Division of the Department of National Health and Welfare. Procurable from the National Film Board of Canada, 400 West Madison Street, Chicago, or 1270 Avenue of the Americas, New York 20.

This film tells the story of John Murray, a reserved hardworking and conscientious young man. The opening scene shows John rather upset about the loss of an important business account. He has feelings of guilt, is unable to concentrate, suffers from periods of despondency and believes that the business is going "on the rocks" because of his own shortcomings. His business associates and his wife are worried by his behavior. The narrator states that John's troubles lie within himself and date back to his early childhood.

John apparently had a happy childhood except for a few incidents, such as a feeling of rejection when his younger brother was born, his mother's annoyance at him for making noise when she became ill and the beating that his father gave him for fighting with Bob, his younger brother, over a snowhouse. After his mother dies, an aunt comes to live with them; she is neither understanding nor sympathetic toward his great emotional needs.

While John is in college, his father dies; he has to give up his ambition to become a writer. He takes over his father's business in order to send his younger brother to college, and Bob's success becomes his own. However, after Bob leaves town, writes a book and is married, John feels so completely alone that he becomes depressed; these events coincide with the loss of the important business account. John cannot admit to himself that he is jealous and resentful of Bob's greater success. Even though he is now happily married, he still does not feel that he deserves this happiness; he becomes a problem and a mystery to his wife and business associates. His difficulty lies far back in his emotional history. The world cannot see and John cannot allow himself to acknowledge his feelings of jealousy. Therefore, he becomes a victim of his conscience and cannot enjoy what he feels he does not deserve.

The presentation of the subject's life to illustrate the illness is very well done, and the effectiveness of the illustration is made stronger by opening with the climax of the subject's life experiences that have resulted in the present illness or depression. With the present illness in mind, the depiction of salient features in the individual's development are more meaningful to the viewer.

This motion picture is similar to others in the series. If taken with the other films, it is more understandable—alone it seems to go into the subject too abruptly, particularly for a nonpsychiatrically oriented audience. It is rather weak on the therapy side; treatment possibilities and the prognosis are mentioned only in passing. However, it is the best in the series.

The child's reaction to unpleasant experiences that are interpreted as rejection by him is vividly done. A weakness is in the gap between episodes in early childhood and early adulthood. Although it may be difficult to film events in the adolescent period, it would be helpful if some attention were given to these years, tying in developments in this period with those of early childhood and the present illness.

The film is suitable for medical students, medical society meetings, general practitioners, social workers, nursery school teachers and nurses. However, a psychiatrist should be present to lead a discussion to the interests of the group seeing the film and to point out the contributions that could be made by that particular group in preventive mental hygiene. The photography and narration are well done.

Laboratory Diagnosis of Influenza: 16 mm., black and white, sound, showing time 17 minutes. Produced in 1950 by and procurable on loan from Communicable Disease Center, 50 Seventh Street, N.E., Atlanta 5 or on purchase ($17.67) from United World Films, 1445 Park Avenue, New York 29.

The diagnosis of influenza consists of isolation of the virus (A, A′, or B) by inoculating chick embryos with washings of the nose and throat during the acute stage of the disease and of demonstration of immune antibodies in the blood about 10 days after onset. The technic of these tests is so lucidly and minutely presented that one gets a much better picture of all procedures than by reading and reviewing of illustrations. Step by step presentation, the emphasis of details, the use of diagrams and closeups, and good narration all contribute to make the viewing of this film a worth while educational experience of special interest to virologists, bacteriologists, public health and general laboratory technicians, medical students and all others who may be interested in the subject. The photography and narration are well done.

Today and Tomorrow: 16 mm., color, sound, showing time 5 minutes. Sponsored by The Muscular Dystrophy Association, 177th Street, and Harlem River, New York 53. Produced by and procurable on loan from Films for Industry, 135 West 52nd Street, New York.

This is a fund-raising film which shows, in the surroundings of a public playground, children who are afflicted with progressive muscular dystrophy. Against this background and with normal children as playmates, the helplessness of these children is accentuated. Their lack of balance and muscular weaknesses are exhibited as they try to play in the manner of normal children. The disease of all the children shown is of the clinical pseudohypertrophic muscular dystrophic type, in various stages of this most prevalent and progressive form.

The film contains a strong emotional appeal which well accomplishes the purpose of arousing the interest of the general public in sufferers of this disease, but it is lacking in specific information as to where these interests can be directed. It would be of interest mainly to lay audiences. The photography and sound are good.

Sodium Citrate in Lead Poisoning.—Four patients were treated for lead poisoning with sodium citrate as the main component of therapy. Lead poisoning was acute in three patients and chronic in one. Doses of 4 gm. of sodium citrate four times daily by mouth for one week to one month were adequate for control of the symptoms. Studies of the lead excreted in the urine in these four cases did not warrant the conclusion that sodium citrate increases lead excretion. Increased coproporphyrinuria was observed during the acute illness in all four of the patients and well before the acute episode in at least two of them. In all patients the urinary lead and coproporphyrin values showed relatively good correlation. In all patients the sign of coproporphyrinuria was seen much earlier than the stippling of red blood cells. The mechanism of the coproporphyrinuria of plumbism is not definitely known.

Obstructive Hydrocephalus in Children.—Hydrocephalus due to an obstruction in the ventricles or subarachnoid spaces is commoner in the infant than is generally supposed. A frequent cause of obstruction in infantile hydrocephalus is the Arnold-Chiari malformation, associated with spina bifida in many patients, especially those with myelocele. Suboccipital exploration was carried out in a number of these cases, without lasting relief of symptoms. Third ventriculostomy, i. e., establishment of a free communication between the third ventricle and the peduncular cisterns was then tried. The transfrontal approach was satisfactory in older children, but did not work out well in infants. Therefore a trial of the lateral or temporal approach was made. This has proved satisfactory in 10 patients with obstructive hydrocephalus associated with spina bifida and presumably due to the Arnold-Chiari syndrome. The patients were followed from six months to four years, and the results were excellent, with cessation of abnormal enlargement of the head and absence of increased intracranial pressure. Ventriculostomy by the lateral or temporal approach should be reserved for patients in whom the cause of the obstruction cannot be readily treated by direct surgical attack and in whom there is no evidence of obstruction of the basilar subarachnoid cisterns. According to the author, it is the procedure of choice for infants with obstructive hydrocephalus due to the Arnold-Chiari malformation.

Occlusion of Internal Carotid Artery.—Eight cases of occlusion of the internal carotid artery in men between the ages of 49 and 68 were studied, four of which were verified by postmortem examination. In two cases arteriographic or surgical confirmation of the diagnosis was made, while in the remaining two cases the diagnosis was made clinically. All the patients were seen on the wards of two general hospitals within a period of six months. Occlusion of the internal carotid artery is much commoner than has heretofore been believed. The clinical picture is highly characteristic, although variable. The basic feature is hemiplegia of rather severe degree, preceded by premonitory paralysis, paresthesia, blindness, dizziness, aphasia, or unconsciousness. Necropsy in the author's cases revealed that the occlusion of the internal carotid artery is usually in the region of the sinus and that the basic pathological process is atherosclerosis. Changes in the brain tend to be localized in the territory of the middle and anterior cerebral arteries, and the extent of the brain lesion may be explained partly by the anatomic pattern of the circle of Willis and partly by other, unknown, factors. Fleeting neurological symptoms, previously attributed to vasospasm, now have a pathological substratum that will serve for their further study. Intermittent, migraine-like headache was frequently observed alternating with the fleeting symptoms. It was steady, never throbbing, and was situated above the ipsilateral eye. Headache usually ceased after the onset of hemiplegia. Hemiplegia of unknown cause in younger persons is often due to disease of the internal carotid artery. The absence of carotid pulsation in the neck during the acute phase of hemiplegia may be diagnostic. Postoperative hemiplegia, as well as stroke following vascular collapse, is often due to thrombosis of the internal carotid artery distal to extreme atherosclerotic narrowing in the region of the carotid sinus. Unexplained cerebral embolism may arise from thrombotic material lying in the carotid sinus.

Changes in the brain tend to be localized in the territory of the middle and anterior cerebral arteries, and the extent of the brain lesion may be explained partly by the anatomic pattern of the circle of Willis and partly by other, unknown, factors. Fleeting neurological symptoms, previously attributed to vasospasm, now have a pathological substratum that will serve for their further study. Intermittent, migraine-like headache was frequently observed alternating with the fleeting symptoms. It was steady, never throbbing, and was situated above the ipsilateral eye. Headache usually ceased after the onset of hemiplegia. Hemiplegia of unknown cause in younger persons is often due to disease of the internal carotid artery. The absence of carotid pulsation in the neck during the acute phase of hemiplegia may be diagnostic. Postoperative hemiplegia, as well as stroke following vascular collapse, is often due to thrombosis of the internal carotid artery distal to extreme atherosclerotic narrowing in the region of the carotid sinus. Unexplained cerebral embolism may arise from thrombotic material lying in the carotid sinus.

The Association library lends periodicals to members of the Association and to individual subscribers in Continental United States and Canada for a period of five days. Three journals may be borrowed at a time. Periodicals are available from 1940 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied with stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted.

Pernicious Anemia and Cancer.—Since the introduction of liver therapy for pernicious anemia there have been reports commenting on the concurrence of pernicious anemia and cancer of the stomach. Authors who favor the idea that there is a connection between the two conditions consider chronic atrophic gastritis a common link. But Weinberg says that this link does not exist. In pernicious anemia there is achylia gastrica, which has nothing in common with achlorhydria but lack of hydrochloric acid. Achylia gastrica is a clinical entity with absolute lack of gastric secretion and disturbance of chymification and motility. The pathological changes are different as well: In achylia gastrica there is no gastritis; in achlorhydria, as it is found in cancer of the stomach, there is pangastritis. Weinberg stresses that achylia gastrica and pernicious anemia have no connection with cancer of the stomach and that they cannot be considered precancerous conditions. It has never been proved whether chronic atrophic gastritis, which leads to achlorhydria, is primary or secondary to gastric cancer. It has been shown, however, that over 80% of all persons in the cancer age have the same gastritic changes as have been found in stomach cancer; these changes are the "physiologic gastritis of old age" and cannot, therefore, be the basis for the development of malignancy. If we eliminate gastritis as a cause, how can we explain the increase in frequency of cancer of the stomach in the course of pernicious anemia found in some statistics? Two explanations have been considered: (1) the prolongation of life in pernicious anemia due to liver therapy and (2) a carcinogenic agent in the liver. The age increase does not seem to be of importance, because both diseases start at about the same age, and the prolongation of life is not sufficiently extensive to be significant. That the development of gastric cancer may be due to a carcinogenic agent in the liver can be demonstrated only by the avoidance of liver preparations and the substitution of stomach preparations that contain the intrinsic factor.

Relationship of Coronary Disease and Peptic Ulcer.—To investigate the correlation between peptic ulcer and coronary occlusion the authors made a survey of 1,522 autopsies. Peptic ulcer was detected in 101 patients (6.6%). The incidence of peptic ulcer was 9% among the 753 patients with arteriosclerosis of the coronary arteries and 10.5% in the 152 patients with coronary occlusion. While this shows a somewhat higher incidence of peptic ulcer in patients with coronary disease, other investigators have found in autopsy studies that peptic ulcer occurred with equal frequency in patients without coronary disease. In the second part of this report the authors give attention to clinical factors common to both diseases. Heightened excitability of the vagus is the common denominator. The diseases are similar in that they occur in nervous, unstable persons, have three basic phenomena (hypersensitivity, hyperirritability, and hyperactivity), occur more commonly among the more intelligent and educated people, have periodicity of symptoms, and similar personality changes. The two conditions generally originate at different age periods, but this may be due to blood vessel changes and to the difference in susceptibility of certain organs at certain ages. The aggravating effects in both are not too dissimilar, and both occur predominantly in males who live and work under stress. In the background of the development of peptic ulcer there are frequently endocrinologic and nervous factors associated with the transition from adolescence to manhood, whereas in coronary disease there is the transition from middle age to presenility. In other words, there may possibly be a similarly acting organic change, vascular in origin, endocrinologically and neurogenically initiated.

ACTH in Beryllium Granulomatosis and Silicosis.—The lesions of beryllium granulomatosis consist of multiple granulomas, increased fibrosis in the interalveolar septa and in the granulomas, and dense collagen deposits. A cellular reaction, predominantly of lymphocytes and mononuclear cells, may be found in the interalveolar walls, between focal lesions, and at the periphery of the nodular granulomas. Pituitary adrenocorticotropic hormone (ACTH) was administered to two patients with chronic beryllium granulomatosis, because this hormone as well as cortisone produces alterations in cellular and fibrous tissue reactions. A striking improvement occurred in both, as evidenced by the clinical response and improvement in x-ray and respiratory function studies. A third patient, similarly treated by others, also improved. Improvement was demonstrated in one patient with silicosis after administration of adrenocorticotropic hormone. The period of observation is too short to permit conclusions as to how long the improvement will persist after cessation of therapy. The appearance of the chest x-rays was unaltered by treatment. Since there has been no adequate treatment for silicosis, further investigation of the effect of adrenocorticotropic hormone seems indicated.

The Crime of Menticide.—The following questions have recently been raised: Is it possible through modern methods to change man's mind in behalf of certain ideological systems, to steal his spiritual freedom, or to compel him to cooperate with tyrannical political systems? Many psychiatric and psychoanalytic problems are touched on by these questions, such as the mishandling or criminal use of transference, mass hypnosis, the dangerous, intelligent madman, the technique of changing personalities (lobotomy, narcohypnosis, and truth serum), artificially provoked regressions with narcotics, and mass intoxication through terror and panic. Political evils force psychiatrists to become more aware of what they are doing, because their activities might be taken over in the service of devious political aims. An organized system of psychological intervention and judicial perversion, in which a powerful tyrant synthetically injects his own thoughts and words into the minds and mouths of the victims he plans to destroy by mock trial, may well be called menticide. The author cites examples of menticide, discusses the techniques it employs, and indicates ways of protection against it.

Diagnosis and Treatment of Gout.—The diagnosis of the early stage of gout is simple; recurrent attacks of acute joint pain with completely asymptomatic intervals, an increase in serum urate, and, eventually, the observation of urate tophi will lead the way to the correct diagnosis, which may be established by the therapeutic test with colchicine. This drug will in most of the cases relieve an acute attack of gouty arthritis, whereas other arthritides are not affected by it. The differential diagnosis of the late stage of gout is sometimes difficult but may be made with the aid of the history of sudden onset of acute attacks, elevated uric acid serum level and the observation of tophi. In the treatment of the acute episode of gout, one tablet (0.5 mg.) of colchicine should be given every hour, or two tablets every two hours, as soon as possible after the beginning of acute symptoms; the drug should be discontinued at the onset of nausea, vomiting, or diarrhea, which usually appear after 10 to 15 doses have been taken. A second course of colchicine after an interval of 48 hours may be required if the first one was not started promptly after the beginning of symptoms. Severe recurrent attacks of acute gouty arthritis may not be relieved, even by repeated massive doses of colchicine, and pituitary adrenocorticotropic hormone (ACTH) offers much promise in cases of this type. Dramatic relief, with subsidence of the acute symptoms within 12 hours, was obtained with a single injection of 80 mg. of pituitary adrenocorticotropic hormone in two men aged 62 and 56 with acute gouty arthritis not relieved by colchicine. A third patient, with a history of long-standing gout, showed little response to a daily dose of 80 mg. of pituitary adrenocorticotropic hormone for four days, but was later relieved by colchicine. In the light of Selye's adaptation theory, any decrease in the adrenocortical activity in a predisposed, gouty patient may precipitate an acute attack. By prompt stimulation of the adrenal cortices with following rebound phenomenon of decreased hormonal activity, such an attack may be elicited after various nonspecific stresses, after cessation of pituitary adrenocorticotropic hormone therapy in the acute episode, or in the interval or chronic stage of the disease. On the other hand, an acute gouty episode can be promptly terminated by pituitary adrenocorticotropic hormone injection in most of the cases, probably because of an increase in adrenocortical secretion in persons with such a deficiency. In this way the disturbing dual action of pituitary adrenocorticotropic hormone in eliciting and terminating an acute attack of gout can be explained.

Intravenous Administration of Fat Emulsions.—The development of a combined fat emulsion derived from the homogenization of coconut oil, gelatin, protein hydrolysate (amigen®), and dextrose solutions provided a new means of parenteral surgical nutrition. The practicability and the benefits of the fat emulsion were discussed in an earlier series of papers. In the present investigation the 10%, the 15%, and the 20% combined fat emulsions were infused intravenously in conjunction with 10% dextrose solution, so that the maximum caloric potential consistent with safe clinical therapy might be attained. The effect of single intravenous infusions of the combined fat emulsion in conjunction with dextrose solution was studied in a series of 19 subjects grouped according to the concentration of fat in the emulsion. The reaction rate averaged 16% for the three groups, with most of the reactions occurring in groups B and C, who received the 15 or 20% combined fat emulsion. Attention was given to systemic reactions, hematologic changes, urinary chemistry, and oxygen consumption. A second series of eight patients were studied from the standpoint of the effect of prolonged injections of the emulsion involving a minimal five day period of therapy. The incidence of reactions in this series was 19%. Clinical studies and pathological examinations showed that the emulsion was well tolerated and could be repeatedly infused for nutritional purposes.

Revascularization of Heart.—McAllister and associates present a progress report on the revascularization of the heart. The beneficial effect of arterialization of the coronary sinus had been demonstrated, but since it is impossible to employ the common carotid artery for the shunt in the human being and since there is no other satisfactory artery in the vicinity of the heart, they inserted a free vein graft between the side of the thoracic aorta and the side of the coronary sinus. They found that the arterial inflow must be restricted by an aortic stoma measuring no more than 3.5 to 4 mm. in diameter. The coronary sinus should not be completely ligated as a preliminary, simultaneous, or subsequent secondary procedure. If it is, too much blood is introduced into the venous tree, so that the pressure approaches aortic levels and blood flow becomes greatly reduced. The excessive pressure causes cardiac failure or myocardial hemorrhage and scarring, and the reduced blood flow results in thrombosis of the grafts. If a vein graft is inserted between the aorta and the coronary sinus and if the sinus is left open so as to create an aortic right auricular fistula, the operation is well tolerated. Forty-seven consecutive patients have been operated on without mortality, and the grafts have remained open in 65% of the cases. This procedure, of itself, furnishes some protection to the heart against occlusion of a major coronary artery. If, at a second stage, the coronary sinus is partially occluded to 3 mm. diameter, there is neither further mortality nor thrombosis of the grafts. Moreover, this two stage procedure has protected 12 of 13 dog hearts against occlusion at the origin of the anterior descending branch of the left coronary artery.

Death Following Stellate Ganglion Block.—A 55 year old woman was given a series of six right stellate ganglion blocks on account of postoperative lymphedema of the arm. From 6 to 12 cc. of 1.5% piperocaine (metycaine®) hydrochloride was used for each block, for which the posterior approach was used. During the second block the patient complained of weakness and dizziness after injection, but when she was put in supine position she felt much better. After five blocks had been done the pain in the arm diminished. When the needle was inserted for the sixth block the patient cried out. Aspiration revealed neither blood nor spinal fluid. After 4 cc. of 1.5% piperocaine was injected, the patient again cried out. On withdrawal of the needle she felt dizzy. She was placed in a semireclining position, and her eyeballs rolled upward and to the right, and respirations and pulse could not be detected. As the result of various measures of resuscitation, the patient was kept alive for 39 hours but then died. The authors cite similar cases from the literature and attempt to relate the sudden cardiorespiratory cessation to vagal arrest of the heart and central respiratory center. They emphasize that the performance of stellate ganglion block requires a thorough understanding of the anatomy and the neurophysiology involved. It should not be considered as a simple procedure to be performed by the untrained.

Cortisone for Adrenal Hyperplasia.—Congenital adrenal hyperplasia causes pseudohermaphrodism in females and macrogenitosomia precox in males. After unsuccessful attempts to suppress the secretion of androgen in patients with congenital adrenal hyperplasia by the administration of steroids, which have a chemical structure similar to that of androgens but possess relatively little androgenic activity, Wilkins and co-workers began to treat these patients with cortisone. This paper presents the results of cortisone administration in six women and two men with congenital adrenal hyperplasia and includes the observations of other investigators in two additional cases. In these 10 cases initial doses of 50 to 100 mg. of cortisone daily in older children or 25 to 50 mg. daily in young infants caused rapid decrease of the urinary 17-ketosteroids. Later, the suppression of 17-ketosteroid excretion was maintained by 25 mg. of cortisone daily, or 50 mg. every other day in older children; doses varying from 10 to 25 mg. per day sufficed in the infants. The effects lasted as long as treatment was continued, the longest period being five to six months. No changes in carbohydrate metabolism were observed. There was an increase in urinary nitrogen excretion suggesting decrease of protein anabolism. In patients with congenital adrenal hyperplasia and defective electrolyte regulation, cortisone probably has some sodium-retaining activity. It is not now possible to decide whether desoxycorticosterone in addition to cortisone is required to maintain electrolyte equilibrium in some of these patients. In most cases the period of treatment has been too short to note definite decrease of virilization. There has been some decrease of acne and seborrhea in a number of cases. In two patients treated for five months, development of the breasts and estrogenic changes of the vaginal smear occurred, and one girl has had four regular menstrual periods. In one patient hypertension disappeared under treatment. In the patient showing Addisonian-like pigmentation, there was considerable fading. Treatment with cortisone in small doses offers the possibility of preventing or suppressing the progressive virilization which occurs with congenital adrenal hyperplasia and may permit the normal development of feminine characteristics in female pseudohermaphrodites.

Anemia in Cancer and Metastases to Bone Marrow.—It is usually assumed that anemia in cancer patients, excluding that due to blood loss or to hemolysis, is due to bone marrow invasion. However, this explanation is not in keeping with the observation that anemia is frequently encountered in cancer patients who have no skeletal changes and inversely anemia may be absent in the presence of extensive bone metastases. Shen and Homburger review morphologic studies of the peripheral blood and bone marrow made in 193 patients with advanced cancer. Of the 50 patients who had evidence of bone metastases 24 were anemic and 26 were not. In 16 anemic patients (eight with and eight without metastases to bone) cobaltous chloride, 60 to 240 mg. daily, was used in testing the bone marrows of these patients for response to such a hematopoietic stimulus. In all six patients with osseous metastases who received an adequate trial of the drug, the administration of cobalt was followed by reticulocyte responses. Of the four patients without metastases to bone who could tolerate cobalt for an adequate period, three showed definite reticulocyte responses followed by increase in red cells, hemoglobin, and hematocrit. The other patient showed no hematologic response. Cobalt therapy in cancer patients with anemia may increase erythropoiesis regardless of metastasis to bone, but it fails to produce subjective improvement and may cause symptoms referable to the gastrointestinal tract or suggestive of angina pectoris. It is concluded that anemia associated with cancer is not usually due to bone marrow replacement by neoplastic tissue.

Hyperthyroidism and Radioactive Iodine.—A Negro girl aged 11 with diffuse toxic goiter and rheumatic heart disease was treated with radioactive iodine. This method of treatment seemed justified since the patient had failed to respond in a satisfactory manner to strong iodine (Lugol's) solution; she had failed to cooperate to the degree necessary to insure success with propylthiouracil, and the risks of surgical treatment by thyroidectomy were increased by the presence of rheumatic heart disease. On admission to the hospital, the patient's temperature was 100.2 F., pulse rate 120, respirations 24, and blood pressure 160/74. The basal metabolic rate ranged from + 45 to + 58%. After it was ascertained by means of a tracer dose of I^{131} that the thyroid would collect radioiodine in a sufficient quantity to suggest a successful radiation effect, a therapeutic dose of radioiodine, i. e., 5 mc., carrier-free, was administered by mouth in a single dose. Except for a gain in weight, there was little change in the patient's clinical course for the first four weeks. The basal metabolic rate dropped abruptly in the fifth week to + 15 and + 23%, in serial determinations, and the pulse fell to an average value of 100. During the sixth week, a decrease in restlessness, exophthalmos, and in tremor of the extremities was noted and the blood pressure fell to 135/85. Mild leukopenia and anemia without thrombopenia occurred during the second week, but the blood cell count then rose rapidly, with the red blood cell count 5,900,000 and the white blood cell count 7,400 at the time of discharge from the hospital five weeks after therapy. Three months after therapy, the patient exhibited no symptoms or signs of thyrotoxicosis other than the mild hypertension and slight exophthalmos. The blood pressure was restored to normal six months after therapy and has remained normal to date. The size of the thyroid gland decreased until it measured approximately 3 by 4 cm., and it has remained that size. Because of the reduction in the basal metabolic rate to subnormal values (lowest reading —35%), the patient was given 0.03 gm. of thyroid hormone by mouth, daily for six months. The patient's clinical course was entirely satisfactory. She returned to school and has been able to engage in normal physical activity. Menarche occurred at the age of 12 years, 2 mo. Menstruation has been regular since. Radioiodine uptake curves of the thyroid gland obtained at the time of treatment and again 21 mo. later are presented. Radioactive iodine should not be the treatment of choice in juvenile hyperthyroidism, but it may be useful in certain selected patients.

Auricular Septal Defects.—Fourteen children, 11 girls and three boys, with evidence of atrial septal defect confirmed by cardiac catheterization are reported on. Three-quarters of the patients were thin, but the other quarter was of an average physique without obesity. A review of the clinical observations in these patients suggests that there is a common pattern that will frequently permit a presumptive diagnosis on physical examination alone. The typical patient is a somewhat thin girl aged 7 whose heartbeat has increased in force and who has a systolic murmur of moderate intensity in the first to third left interspaces. The murmur is not accompanied by a thrill, but is usually associated with an accentuated second heart sound down the left border of the sternum. The electrocardiogram usually shows right axis deviation, and under the fluoroscope one sees a slight to moderately enlarged heart with increased and pulsating hilar shadows, and the pulmonary trunk is usually bulging. A close approximation of this pattern was observed in most of the author's 14 patients. Accurate diagnosis of auricular septal defects permits proper management of physical activity of the patient and choice of cardiac surgery to correct the defect. One female patient, aged 10, was operated on. Silk sutures were passed through the plane of the auricular septum. These were drawn taut and tied in an effort to close or eliminate the opening between the auricles. The patient had a satisfactory convalescence from the operation. There was moderate improvement in exercise tolerance following operation, which was sustained for six to eight months. A generalized decrease in the size of the right auricle was demonstrated on roentgenologic examination. The optimum surgical correction of an auricular septal defect will be difficult to achieve by present techniques, but results obtained in the case reported on suggest that the problem is not insuperable. Untreated patients with auricular septal defects survive approximately two-thirds of the normal life span.

Papaverine Treatment for Spasm of Pylorus in Infants.—Several hundred infants with spasm of the pylorus were treated with 0.01 gm. of papaverine hydrochloride daily by mouth during the period 1913-1949. Recovery occurred only in cases in which diagnosis was made early. Only a partial effect or no effect whatsoever may be obtained with this method of treatment in the presence of a hypertrophic tumor in the pyloric sphincter. This applies even more to cases of secondary stenosis of the pylorus in which the largest doses of papaverine hydrochloride proved ineffective and in which surgical treatment is indispensable. Spasm of the pylorus frequently occurs in the absence of hypertrophy of smooth muscle in the allergic syndrome of newborn infants. Early treatment of this allergic spasm provides effective prophylaxis against the later occurrence of hypertrophic stenosis of the pylorus, since in the absence of treatment the latter may develop from the primary functional spasm by increased muscular activity resulting in a tumor of the muscle with secondary stenosis. In addition, treatment of an allergic spasm of the pylorus with papaverine hydrochloride may effectively relieve serious disturbances of breast feeding and early nutritional disturbances of newborn babies. Combined administration of a daily dose of 0.01 gm. of papaverine hydrochloride with 0.05 gm. of aminopyrine in powder form by mouth is recommended before breast or bottle feeding. This dose may be repeated three to four times within 24 hours according to the age of the infant and the severity of the condition. Suppositories, drip enemas or injections of pure papaverine hydrochloride may be given if oral administration is impossible because of severe vomiting. In cases of simultaneous abdominal pain and diarrhea in newborn infants, combined treatment with codeine and aminopyrine is recommended, but papaverine hydrochloride remains the basic drug for antispasmodic therapy. The author stresses the importance of the neuropathic factor in pyloric stenosis of nursing infants.

Senile Ankylosing Hyperostosis of Spine.—The clinical and radiological study of nine cases, combined with necropsy findings in two specimens, enabled Forestier and Rotes-Querol to set out some of the clinical, pathologic and radiological features of a specific condition among the ankylosing diseases of the spine. The condition is to be differentiated from ankylosing spondylitis, and the authors propose for it the term "senile ankylosing hyperostosis of the spine." This name emphasizes: (*a*) the hyperostosis, a most striking pathologic element, and (*b*) two constant clinical features: spinal rigidity and advanced age. It is not a rare disease, but most often either goes unnoticed or is mistaken for some other form of vertebral ossification. Because of the mild nature of the symptoms no active treatment is required. Roentgenologic examination reveals bony outgrowths or hyperostoses that arise from the anterolateral aspect of the vertebral bodies and grow upward in a "candle flame" formation over the lumbar disk spaces; at the level of the dorsal disks they are often thickened. They have a bony structure with a dense cortex similar to that of the head of the femur, the cancellous bone being in continuity with that of the vertebral bodies. They may coexist with osteophytes, but have entirely different anatomic features.

Prognosis of Breast Carcinoma.—In a recent investigation Bloom had stressed the significance of the histologic architecture of the tumor in cases of mammary carcinoma. A classification based on the microscopic appearance of the tumor (grade) combined with a knowledge of its extent (stage) was found to provide a more reliable guide to prognosis than could be achieved by either grading or staging alone. In the present report Bloom is concerned with some further aspects of prognosis of breast cancer. No significant differences in outcome were revealed in the various age groups, the younger women faring no worse than the older ones. The incidence of tumors of low and also of high malignancy in the various decades was practically the same. It is useless to try to assess the effect of the delay in seeking treatment without reference to the histologic type of growth involved. For example, delay is of little importance for patients with highly malignant (grade 3) tumors; it does not seem to matter whether such patients are treated early (less than six weeks) or late (six to 12 months), the prognosis is equally bad. On the other hand, the time factor appears to influence the outlook of women with growths whose behavior is essentially more benign (grade 1). In this type of case a loss of more than six months means a substantial fall in the survival rate. The site of the tumor in the breast was found to exert no striking effect on prognosis. It is possible, however, that the outlook for patients with growths of low grade malignancy may be influenced slightly by this feature. The size of the primary growth influences prognosis, particularly in the intermediate grade of tumors, but size was evidently of no prognostic importance in either low or high grade malignancy. Pregnancy following the adequate control of previous mammary carcinoma does not appear to influence the outlook adversely.

Sulfonamides and Tonsillitis.—A study was made of the effectiveness of sulfonamides in the treatment of 82 cases of acute tonsillitis. The cases were divided equally into treated and control groups. Fifty tablets (25 gm.) of sulfatriad (37.5% sulfadiazine, 37.5% sulfathiazole and 25% sulfamerazine) were given to each patient in the treated group; each patient in the control group received 50 lactose tablets. All the patients were treated by bed rest and given copious fluids. Analysis of clinical records revealed no difference between control and treated cases in regard to the speed of recovery from various symptoms (temperature, edema, exudate, adenitis and pain) regardless of the presence or absence of beta hemolytic streptococci. However, judged by their over-all clinical appearance, the treated patients seemed to recover more rapidly. The administration of sulfatriad had no effect on the survival of beta hemolytic streptococci in the cases examined. The authors conclude that the findings do not justify the routine use of a potentially dangerous drug such as sulfatriad in the treatment of acute tonsillitis. They feel that other methods can be found to improve the well-being of the patient if the difference of recovery is only a matter of hours.

"Sore Throat" in General Practice.—Landsman and his associates are concerned with the epidemiology and best method of treatment for "sore throat." Their study is based on 100 patients who complained of sore throat as the leading symptom. Throat cultures showed a normal flora in approximately one third of the patients; a heavy growth of beta hemolytic streptococci was evidenced in a similar proportion; a few colonies were seen in 22%, and a moderate growth of beta hemolytic streptococcus in 14% of the patients. Therefore, the authors state that less than half the cases (46%) can be regarded as streptococcal in origin. This observation is important since it is a common misapprehension that acute tonsillitis almost always implies a streptococcal origin. About one fourth of the streptococcal cases were not exudative. Twenty-six patients were given sulfanilamide (0.5 gm.); 26 were given 0.5 gm. of sulfatriad (37.5% sulfadiazine, 37.5% sulfathiazole and 25% sulfamerazine), and 43 were given lactose tablets. The results of the therapeutic trial did not support the thesis that sulfonamides exert a beneficial effect in the treatment of acute tonsillitis. Neither of the sulfonamide tablets was appreciably superior to the lactose tablet, which presumably was therapeutically inert. The average duration of fever and pain in those patients treated with lactose was exceedingly short, namely, 1.07 and 1.95 days respectively. The authors conclude that in the treatment of acute tonsillitis it is unnecessary as well as expensive to use drugs, such as the sulfonamides, that have definite and known dangers.

Pregnancy Test with Male Toad.—Tien and co-workers began in March 1949 to use male toads for pregnancy tests. The toads were captured in the fields and vegetable gardens in the region of Shanghai and might be classified as Bufo bufo asiaticus Steindachner. The test was made with 5 cc. of untreated morning urine. A total of 1,060 pregnancy tests was made. The accuracy was 97.8% in 333 tests on 306 healthy pregnant women. The accuracy rate was only 89.73% in 877 tests on women with various types of pathologic conditions associated with pregnancy, such as abortion, ectopic pregnancy, hydatidiform mole and choriocarcinoma. Detachment of the placenta from its site of implantation in most cases of tubal abortion and rupture, and the degeneration of placenta tissue in cases of old ectopic gestation, and technical errors and insensitivity of the test animals explained some of the erroneous results. No false positive test was found among 248 tests made in various gynecological conditions unassociated with pregnancy. Thirty international units of chorionic gonadotropin was found to be the minimal dose necessary to produce a positive reaction in the average male toad in the spring. The accuracy rate was 60.6% in 99 cases of ectopic pregnancy. The test might serve as a diagnostic aid in ectopic pregnancy when results are positive; however, a negative result could not rule out the possibility of ectopic pregnancy. The urine in five cases of choriocarcinoma did not have a higher concentration of chorionic gonadotropin than in cases of hydatidiform mole by quantitative determination. Results of the pregnancy test became negative after the evacuation of the products of conception much sooner in normal pregnancy, abortion and ectopic gestation than in cases of hydatidiform mole. In the former group, results of the test might remain positive to the third day after evacuation, while in the latter results usually remained positive until the ninth day.

Nederlandsch Tijdschrift v. Geneeskunde, Amsterdam

95:169-264 (Jan. 20) 1951. **Partial Index**

Rare Cutaneous Lesion (Angiokeratoma Corporis Diffusum) as Symptom of a Hitherto Unknown Disturbance in Phosphatide Metabolism (Thesaurismosis). M. Ruiter.—p. 184.
*Occupational Paralysis of Ulnar Nerve. J. G. Y. de Jong and J. G. Geerling.—p. 192.
*Significance of Price-Jones Curve in Hemolytic Disease of the Newborn. S. I. de Vries.—p. 201.

Occupational Paralysis of Ulnar Nerve.—In a radio tube factory, paralysis of the ulnar nerve developed in eight inspectors. The fact that these workers leaned both elbows against a hard table is regarded as largely responsible for this paralysis. However, other contributing factors were searched for. A thorough neurologic examination was combined with inquiry into the diet, the misuse of alcohol or tobacco and a possible hereditary predisposition to neuritis. The scalenus syndrome was searched for; the musculature was tested electrically, and the cervical vertebrae were examined by roentgenoscopy for detection of possible cervical ribs. The lungs and the lumbosacral vertebrae were also examined roentgenologically. The histories of the eight patients are given. Treatment consisted largely of galvanotherapy and administration of vitamins. This treatment effected improvement, but in some cases mild hypesthesia remained. Rubber sponge pads were placed under the elbows of the radio tube inspectors to prevent this injury to the ulnar nerve. This measure proved effective.

The Price-Jones Curve in Hemolytic Disease of the Newborn.—The hematologic disorders that develop in newborn infants as the result of Rhesus-factor antagonism in the parents may appear not only in the form of icterus gravis, congenital anemia and fetal hydrops but also in milder forms, which may not be recognized clinically. De Vries has demonstrated changes in the Price-Jones curve of the erythrocytes in newborn infants with hemolytic disease. He made studies on 60 newborn infants with hemolytic disease, belonging to six different groups of 10 infants each. The first four groups were Rh-positive infants born at term to (1) an Rh-positive mother, (2) an Rh-negative primipara, (3) an Rh-negative multipara and (4) an Rh-negative primipara or multipara. The infants of group 4 differed from those in groups 2 and 3 in that their reaction to the Coombs test was positive, whereas results were negative in groups 2 and 3. The infants in groups 5 and 6 were prematurely born Rh-positive children, those of group 5 having an Rh-positive, those of group 6 an Rh-negative mother. The author found that qualitative changes in the Price-Jones curve were of greater significance than the absoeration of the most important aspects of studies in heredity, there is an introductory chapter providing orientation, followed by chapters on Mendelian inheritance, crosses, sex-linked and lethal genes, the mapping of chromosomes and numerous other related topics. The genetics of domestic animals and cultivated plants are also discussed. Other important chapters are devoted to sex determination, the mutant gene in man, eugenics and analysis of family histories. Profusely illustrated with sketches, diagrams and photographs, including one in color on blood groups, the volume is printed in clear, well leaded type that is conducive to easy reading. It should have widespread appeal.

Symposium on the Healthy Personality: Transactions of Special Meetings of Conference on Infancy and Childhood June 8-9 and July 3-4, 1950, New York, N. Y. Edited by Milton J. E. Senn, M.D. Supplement II: Problems of Infancy and Childhood, Transactions of Fourth Conference, March, 1950. Cloth. $2.50. Pp. 298. Josiah Macy, Jr. Foundation, 565 Park Ave., New York 21, 1950.

To lay a factual background for the consideration of "healthy personality development of children and youth" and "how can we rear an emotionally healthy generation," a group of neuropsychiatrists, psychoanalysts, psychologists, pediatricians, obstetricians, anthropologists and sociologists met with members of the Fact Finding Committee of the Midcentury White House Conference and its staff. This volume is a stenographic report of the papers and discussions of these two meetings.

The first meeting concerned the discussion of a preliminary report on "Growth and Crisis" by Erik H. Erikson, a psychoanalyst with the Institute on Personality Assessment and Research of the University of California, Berkeley, Calif. He presented the criteria of a healthy personality in the eight stages of development at which he feels a person passes through a developmental crisis. His colleagues discuss his point of view very criti[illegible]ly, with the hope of making his final report, which follows [illegible] discussion, more useful to the White House Conference.

The second session considered two presentations. "Constitutional and Prenatal Factors in Infant and Child Health" by M. T. Ashley Montagu of the Department of Anthropology, Rutgers University, New Brunswick, N. J., covered the information available on the effect of the prenatal environment on the subsequent emotional development of a person. The second, "Toward a Social Psychology of Mental Health" by Marie Jahoda of the Research Center for Human Relations, New York University Graduate School of Arts and Sciences, purports "to examine what is known and what should be known about the impact of community influence on the mental health of the individual."

The interesting part of this book is the profound discussion of developmental problems by scientists of widely varying education and experience. The semantic problems of interprofessional communication are clearly presented in the effort each participant makes to understand the thinking behind the words used. This book also presents an excellent overview of the thinking not only of these three authorities, but also of the many equally well informed members and guests of the conference.

Any physician concerned with children, particularly with their emotional growth and personality development, will find these carefully recorded conversations a stimulating experience. Many of the thoughts that the Fact Finding Committee presented to the Midcentury White House Conference had their origin in these two sessions recorded in this book.

Kurzgefasstes Lehrbuch der orthopädischen Krankheiten. Von Professor Dr. Peter Pitzen, Direktor der orthopädischen Universitäts-Klinik und Poliklinik (Hüfferstiftung), Münster i. Westf. Fifth edition. Cloth. 17.40 marks. Pp. 286, with 213 illustrations. Urban & Schwarzenberg, Thierschstrasse 11, München 2; Meinekestr. 13, Berlin W. 15, 1950.

This book is written for the general practitioner so that he may become acquainted with the commoner orthopedic conditions encountered. The author states that it is designed to help the physician obtain a clear conception of certain physical conditions, which "in a way have remained diagnostic stepchildren in spite of their relative frequency and significance in regards to public health."

The style of the text is termed by the author "telegraphic." He has used this style in previous editions, but on many occasions he abandons it to give place to fuller descriptions of symptoms.

The subject material is well chosen, although some conditions, such as severe congenital defects of the extremities, could have been omitted in favor of other commoner ones such as bone tumors. Osteoid osteoma, a pathologic entity, recently described and investigated, is not mentioned.

The chapter dealing with orthopedic conditions of the foot and hip is particularly well done. It is remarkable how much diagnostic material may be embraced in a few pages. In some instances, conservative procedures are overemphasized, procedures which in the present light of our knowledge can hardly be accepted or justified. An example in point is the statement that satisfactory correction of a scoliotic deformity may be achieved by "muscle power." Modern opinion disagrees with this.

Surgical interventions are only casually referred to, perhaps with some justification, because the work is intended for general practitioners. Some mention, however, should have been made of the modern surgical treatment of scoliosis. Important and frequent orthopedic conditions, such as ununited fracture of the femur, are not mentioned. The description of the surgical treatment of malum coxae senilis, which for some reason the author calls arthrosis deformans of the hip, is poorly presented. The illustrations are numerous and good. The radiograms are equally satisfactory. As a whole, the book is well written and may be read with benefit by the general practitioner who reads German. A bibliography would have enhanced the value of the work, particularly for the student.

Chirurgie esthétique nasale. Par Marcel Galtier. Préface de M. Bouchet. Paper. 2000 francs. Pp. 233, with 172 illustrations. G. Doin & Cie, 8 Place de l'Odéon, Paris 6^e, 1950.

The first two sections of this book deal with development and surgical anatomy, respectively. The discussion of surgical anatomy, although inclusive, seems somewhat abbreviated in specific details. A section on artistic anatomy is interestingly presented. This part is very well written and cleverly presents variations in the nasolabial angle and classifications of the different types of profiles. An interesting discussion follows on the "photometer" and its relation to the various profiles. The different anomalies are also presented. Less than two pages are devoted to the physiology of the nose, which is probably the weakest section of the book. Sections on armamentarium and anesthesia are well done, as are the numerous procedures that are described to correct the various types of nasal deformities. Much space is devoted to preoperative and postoperative photographs. However, it would have been well in each instance to show both front and side views. The illustrations are well done and depict the procedures clearly. For anyone able to read French this book can be recommended as a good collateral source on the subject of nasal plastic surgery.

Personality and Psychotherapy: An Analysis in Terms of Learning, Thinking, and Culture. By John Dollard, [illegible] (Professor), and Neal E. Miller, Profes[illegible] Human Relations, Yale University, New Haven. [illegible] 19 illustrations. McGraw-Hill Book Company, Inc., 330 W. 42nd St., New York 18; Aldwych House, Aldwych, London, W.C.2, 1950.

This book is addressed to students, teachers and research workers in the fields of personality adjustment, abnormal psychology and psychotherapy.

The authors have attempted to bring together in integrated form recent thinking in the fields of psychoanalysis, experimental methods of natural science and modern sociology, and anthropology. The purpose is to establish an overall psychologic basis for a general science of human behavior. In the hypotheses presented, the authors have drawn from the works of Freud, Pavlov, Thorndike, Hull, Sumner, Murdock, Kluckhohn and Warner. An attempt has been made to integrate a wide range of material, which includes the basic principles of learning, the understanding of socially learned drives, dynamics of conflict and the normal use of the mind in the solution of problems of childhood, neurosis and self study.

This book is a valuable contribution toward bringing about a unified concept of the fields mentioned as they relate to our culture.

The Amino Acid Composition of Proteins and Foods: Analytical Methods and Results. By Richard J. Block, Ph.D., Associate in Department of Physiology and Biochemistry, New York Medical College, New York, and Diana Bolling, B.S. Second edition. Cloth. $10.50. Pp. 576, with illustrations. Charles C Thomas, Publisher, 301-327 E. Lawrence Ave., Springfield, Ill.; Blackwell Scientific Publications, Ltd., 49 Broad St., Oxford, England; Ryerson Press, 299 Queen St., W., Toronto 2B, 1951.

This edition brings to the reader a revision which includes advances in the analysis of amino acids since 1945. The extended use of microbiological methods has been a major development in this field actually from about 1943.

Whenever possible, several procedures are given for the estimation of each amino acid. Whenever identical results were obtained by two widely different methods, the author emphasizes the point with regard to the confidence that is engendered thereby for each method.

For the food faddist and inveterate meat eater, the author makes an interesting observation that an essential amino acid is essential whether it comes from animal or vegetable protein. On this basis, the conclusion is drawn that it is just as arbitrary to make a distinction between plant and animal proteins as it is to draw a distinction for the carbohydrates.

The relative values of chemical and microbiological assays are appraised. The author considers that a combination of the chromatograph and chemical methods will yield the most significant results in the study of the structure of proteins and peptides. The microbiological procedures, on the other hand, will probably be of most value in the routine analysis of foods and feeds.

To the physician, this treatise would demonstrate the tremendous work of the supporting sciences of chemistry and biology in the advancement of knowledge incident to the important public health field of nutrition, which is a potent and basic prophylactic tool available to medical practitioners.

In presenting to the average reader the widely scattered literature on methods and results of protein analysis, this publication serves a very useful purpose.

The 1950 Year Book of Drug Therapy (October, 1949-September, 1950). Edited by Harry Beckman, M.D., Director, Department of Pharmacology, Marquette University School of Medicine, Milwaukee. Cloth. $5. Pp. 566, with 88 illustrations. Year Book Publishers, Inc., 200 E. Illinois St., Chicago 11, 1951.

The major portion of this textbook is devoted to abstracts of drug advances in the various major branches of practice, with editorial comments to highlight controversial points. Possibly, the best portion of the book is its introduction, in which the editor reviews the advances in drug therapy during the decade 1940 to 1950 in a concise thoughtful resumé.

A plea is made for physicians to realize that the socioeconomic impact of increased life span requires emphasis to the public that this increased longevity and freedom from infectious diseases materially increases the capacity to work of our older generations. In the opinion of the editor, some method must be evolved to absorb the productive capacities of elderly persons into industry if we intend to resolve some of the difficulties of geriatric patients.

The Folklore of Sex. By Albert Ellis, Ph.D. Cloth. $5. Pp. 313. Charles Boni, 3 Grove Court, New York, 1951.

Uniqueness marks the manner in which this survey of modern attitudes regarding sex was carried out by Ellis, who, in dedicating the volume to Havelock Ellis, notes with regret that they are not related. After considering various approaches, he settled on the plan of scanning all popular mediums of mass communication for a one day period. The day selected by Ellis was Jan. 1, 1950. What he found relating to sex aspects in that extensive, even though one day, survey is reported and analyzed under various classifications. In part 1 he determines popular attitudes on extramarital relations, and in successive sections he covers noncoital relations, sex relations involving pregnancy, sex organs, desires and expressions, sex crimes and "perversions," and sex control and censorship. The sections vary considerably in length, some taking little more than a few pages. All are filled with direct quotations from daily papers, popular magazines—"slick paper" as well as the "pulps"—at all levels from family to cartoon and "laugh" publications, books, the legitimate stage, radio, television, and motion pictures. The findings constitute a surprising haul that will amuse some, shock others and move still others to "I-told-you-so" comments.

In addition to providing running discussion of what he culls from the array of sources consulted, Ellis has a special section on statistical considerations and another termed "Summing Up." Numerous tables are contained in the first chapter of the former.

Ellis has made an important contribution in this field, and, because it does not depend on interviews or personal opinions other than those of the researcher, it can be accepted as more enlightening than many other sex surveys. After accompanying Ellis on his tour, one must conclude that sex is an important subject, since there is so much of it being constantly paraded. The author suggests three eventualities: learning to tolerate the present contradiction between liberal and conservative views, further liberalization in that respect, or a return to a distinctly conservative attitude. He offers no opinion as to what it will be.

In a bibliography are listed all the sources consulted, and it is an imposing array.

Bases of Human Behavior: A Biologic Approach to Psychiatry. By Leon J. Saul, M.D., Professor of Clinical Psychiatry, University of Pennsylvania School of Medicine, Philadelphia. Cloth. $4. Pp. 150, with 8 illustrations. J. B. Lippincott Company, 227-231 S. 6th St., Philadelphia 5; Aldine House, 10-13 Bedford St., London, W.C.2; 2083 Guy St., Montreal, 1951.

This book presents an introduction to the basic theories of dynamic psychiatry and considers the relation of these theories to present day concepts of physiology, with particular reference to new theories concerning the physiologic effects of stress. Stress is considered to be either a reactive type arising from the conflict of a person with his environment, or an inner type arising from basic emotional conflicts that develop in childhood. An attempt is made to follow the impact of psychic and emotional tension through to physiologic end-point reactions on body tissues. The style of the book is simple and clear. It should be of considerable value to beginning students of medicine in clarifying the theoretic concepts that underlie the expanding field of psychosomatic medicine.

Taschenbuch der Anatomie. Band 2: Gastropulmonalsystem (Verdauungs- und Atmungsorgane), Urogenitalsystem (Harn- und Geschlechtsorgane), Gefässsystem. Von Professor Dr. med. Hermann Voss und Dozent Dr. med. habil., Dr. phil. Robert Herrlinger. Third edition. Half-cloth. 12 marks. Pp. 340, with 204 illustrations. Gustav Fischer, Villengang 2, Jena 15, Germany, 1950.

This admirable little book measures only 118 by 158 mm. Nevertheless, it covers the gastrointestinal, respiratory, urogenital, cardiovascular and lymphatic systems with precision and in detail. The 204 diagrams are all labeled with unabbreviated names pointing directly to the intended parts. It has a good index and even a short bibliography. All this is achieved, by some miracle of the printer's art, without sacrifice of legibility in either text or legends. The book will be handy for anatomy students who can read German, and it should also be studied as a remarkable example of pocket-sized textbooks of good quality.

Facts About the Menopause. By Maxine Davis. Cloth. $2.50. Pp. 172. McGraw-Hill Book Company, Inc., 330 W. 42nd St., New York 18; Aldwych House, Aldwych, London, W.C.2, 1948-1951.

The purpose of this volume is to prepare the woman approaching the menopause for this transitional period in her life. The many misconceptions prevalent in our folklore concerning the climacteric are discussed, exposed to scientific analysis and disposed of as largely false. The physiology, endocrinology, symptoms and usual treatment of the menopause are reviewed in simple, understandable language. Questions concerning libido, sex life and personal hygiene are answered. The author gives too much prominence to the climacteric in men when one considers the relatively low incidence of the syndrome in men as compared to women. The book makes good reading for the physician to recommend to his menopausal patients.

QUERIES AND MINOR NOTES

ABSCESSED TEETH

To the Editor:—*I frequently see children with swollen jaws resulting from abscessed teeth. They seem very ill. They have been to their dentist, but he tells them to wait, as the tooth cannot be pulled until it "cools down." Is it not true that pus anywhere should be drained promptly and that with antibiotics there is much less danger of septicemia if the tooth is pulled than if the tooth is left in? Many dentists do not know how to use penicillin. Should they not pull such a tooth and refer the patient to the physician for antibiotic treatment? Is it that important to save an infected tooth, for alignment's sake, that a child should be allowed to suffer so many days? I would appreciate some discussion.*

David Hoehn, M.D., Holdingford, Minn.

This inquiry was referred to two authorities, whose respective replies follow.—Ed.

Answer.—The above question illustrates one of many instances wherein the patient will benefit by the cooperative efforts of the dentist and physician. Prior to the advent of the antibiotics, teeth were not usually extracted during the acute phase of such an infection, although when indicated incision and drainage of abscesses were performed. Today with adequate preoperative and postoperative antibiotic therapy, extraction of the offending tooth when necessary is usually not contraindicated. Many dentists prefer not to administer drugs parenterally and consequently welcome the cooperation of the physician. The physician, however, should have the opportunity to examine the patient and prescribe and administer proper medication preoperatively. Such infected teeth most often cannot be saved. Obviously the tooth must be sacrificed if the patient's health is endangered. The deciduous and first permanent molars are the most frequent offenders. Although early loss of these teeth may lead to malocclusion, it can be prevented by maintenance of the space created by loss of the tooth by means of a dental appliance.

Answer.—There can be little question that gums should be drained by incision as soon as one is sure pus is present. Often the infected tooth may be removed at the same time, but sometimes this procedure must be delayed until cellulitis of the soft parts has subsided and there is definite evidence of localization. There is no question, also, that depot penicillin in doses of at least 400,000 units one hour before the time of surgery offers considerable protection against bacteremia. In case of badly infected teeth, the depot penicillin should be repeated at intervals of eight to 12 hours until the infection has subsided. The decision as to the time of the surgical procedure should be the joint responsibility of the extractionist and the physician. No infected tooth should be retained for the purpose of alignment or for any other reason.

NECROBIOSIS LIPOIDICA DIABETICORUM

To the Editor:—*Is there any new therapy for necrobiosis diabeticorum?*

M.D., New York.

Answer.—There is no specific therapy, new or old, for necrobiosis lipoidica diabeticorum. Careful control of the diabetic condition, local cleanliness, watchful waiting and protection of the affected area to prevent further injury are best measures. Long years of observation show that almost invariably the lesions subside eventually and a few so completely as almost to obscure the original lesion. Even the worst cases improve, but time appears to be the factor of chief importance.

CHEST PAIN FOLLOWING INHALATION OF COLD AIR

To the Editor:—*A 50 year old man complained of severe pain in his chest on inhalation of cold air, followed many times by hemoptysis. His chest x-ray appeared within normal limits as did the cardiac shadow. Bronchoscopy and bronchograms disclosed no abnormalities. Smears were made from the bronchial tree; cytological study did not disclose cancer or other abnormality. I would appreciate any help in diagnosis and treatment that might be followed.*

W. H. Brady, M.D., Gooding, Idaho.

Answer.—The problem presented in the case reported is somewhat obscure. There are persons who react violently to too much cold air. This has been designated by some allergists as cold allergy, or allergy to physical agents. It seems to be an oversensitive condition of the bronchial mucosa, or the nerve endings in the bronchial mucosa.

Of recent years there has been a great deal of information obtained about virus infections of the bronchi. Many of these infections begin in the mucosa and cause a profound irritation, with reaction to cold air. If there is access to a good virus laboratory, a sample of the sputum should be studied for virus.

The treatment of either one of these conditions would be essentially the same. If virus proves to be causative, aureomycin may help. In severe virus infections of the bronchial tree, however, an immediate transfer to a warm climate has been found to be effective. If this is not possible, an air-conditioned, warm room is advocated. Otherwise, the patient will have to be treated by the ordinary heating facilities available, and with hot packs when the irritation becomes too severe, with the possible addition of sedative cough mixtures.

EXOPHTHALMUS

To the Editor:—*Has there been anything found that will help exophthalmus following hyperthyroid? A patient was subjected to thyroidectomy April 17, 1950. The present basal metabolic rate is + 8. The patient has chronic irritation of the conjunctivas probably due to exposure to air.*

Eugene C. Lowe, M.D., Miami, Fla.

Answer.—The exophthalmos that accompanies Graves' disease is not the result of the hyperthyroidism itself; hence removal of the thyroid does not as a rule cause any striking change in the exophthalmos. The same is true of treatment with radioactive iodine or with the antithyroid drugs. Oftentimes the appearance of exophthalmos improves, because after correction of the hyperthyroidism the widening of the fissures decreases, but the actual position of the eyes usually remains about the same. Conjunctival irritation is due to failure of the lids to close, and this oftentimes can be corrected by tarsoplasty, in which the corners of the lids are sewn together to narrow the aperture a little. Boric acid ointment can be used under the lids; if edema is present it is wise to advise the patient to sleep in a sitting position. The eyes should be shielded from the wind at all times.

FRUIT JUICES AND ATOMIC BURNS

To the Editor:—*Are orange and grapefruit juices contraindicated in the treatment of burns, atomic or otherwise, because of the high potassium content of these juices? Can you refer me to literature on this subject?*

May R. Mayers, M.D., New York.

Answer.—There is no present evidence that orange and grapefruit juice are contraindicated in the treatment of atomic burns. Studies on potassium levels in burns have been done by Moore, Longohr, Ingebretsen and Cope (*Ann. Surg.* **132**:1, 1950) and Crossweller, Farmer and Franks (*Brit. M. J.* **2**:242, 1950).

The answers here published have been prepared by competent authorities. They do not, however, represent the opinions of any official bodies unless specifically stated in the reply. Anonymous communications and queries on postal cards cannot be answered. Every letter must contain the writer's name and address, but these will be omitted on request.

SUBSTANCES USED TO STIMULATE FIBROUS TISSUE

To the Editor:—*To what extent is polyethylene (polythene®) being recommended in surgical cases requiring fibrous tissue formation? Have any studies been published on dicetyl phosphate in human subjects for the same purpose (fibrous tissue formation)? Are any other substances being used to stimulate fibrous tissue formation? I am familiar with results published on polyethylene in hernia and aneurysm; has it been used for any other conditions?*

Nelson Libanio, M.D., Rio de Janeiro.

Answer.—Polyethylene is being used frequently by a number of investigators and clinicians as a vehicle or framework for holding irritating substances in place in an area of the body where fibrosis is desired. The use of polyethylene in this role as a support for irritants represents only a small fraction of the clinical use of the material, most of which is employed in its pure form to avoid any foreign body reaction. This inert property of pure polyethylene permits its use as temporary or permanent prosthesis in reconstruction of strictures or defects in large arteries, bile ducts, bronchi and interventricular cerebral ducts as well as nonirritating coverings for the brain, tendons and similar situations where fibrosis would be harmful. Polyethylene film has been recommended for use as a protective sheath under metal bands used to progressively constrict large arteries. This sheath prevents pressure necrosis of the vessel wall at the edge of the metal band according to P. C. Shea. A search is being made now for suitable absorbable substitutes for polyethylene, which represents a permanent sheet of nonabsorbable material. The gradual absorption of this film would avoid complications such as reoperation for removal of the polyethylene, which may prevent healing when an infection occurs, as has been reported in one instance.

Dicetyl phosphate has been isolated by Yeager and Cowley as the irritating factor in the original impure polyethylene manufactured by the solvent cast process, the use of which has been discontinued by some manufacturers. Pure polyethylene film is now being impregnated with dicetyl phosphate powder by rubbing of the powder into the film while it is softened by heating. Difficulty has been encountered in sterilization of the polyethylene film without removal of the water and alcohol soluble dicetyl phosphate. Repeated phosphate analysis of both the film and the sterilizing solution by Dr. W. R. Todd of the biochemistry department at the University of Oregon Medical School indicates that soaking the impregnated film in 1: 1,000 aqueous benzalkonium chloride solution for 20 minutes removes less of the dicetyl phosphate than other methods of sterilization. Although dicetyl phosphate has been used in a number of patients for production of fibrosis, there appear to be no published data on postmortem findings in humans. Yeager and Cowley, as well as Poppe, have observed a pronounced fibrous tissue reaction around the dicetyl phosphate in dogs.

Substances other than dicetyl phosphate that have been used to stimulate fibrous tissue are numerous. Cellulose hydrate, the common type of cellophane, is probably the most frequent, but the variable factors and sizings used in its manufacture have made its reactions somewhat unpredictable. Asbestos powder, as recommended by Claude Beck for creating vascular adhesions in the pericardial cavity, has been used clinically, but here again the irritating properties of asbestos vary with the manufacturing process. Talcum glove powder has been shown by a number of investigators to produce intestinal adhesions and has been used by Poppe when a small aneurysm has been encountered unexpectedly and other preparations were not readily available. Rosaniline dye has been used in animals to produce fibrosis but, as indicated by early animal experiments (Poppe and Renault), proved too toxic for clinical application.

Polyethylene containing dicetyl phosphate has been used primarily in reinforcing aneurysms and hernia repair. Other uses consist of wrapping it around the patent ductus or carotid artery in cases of cerebral aneurysm to produce slow but progressive development of strictures and stenosis.

HAIR DYES

To the Editor:—*A patient requested information on a reliable hair dye. I was unable to help her, and I did not wish to suggest any one product without the opinion of the American Medical Association.*

Wilfred Yoslow, M.D., New York.

Answer.—Certain general precautions are indicated in the use of most hair dyes. While the incidence of unfavorable reactions is low, they do occur and they are usually due to the lack of adequate directions for use, carelessness on the part of the user or a sensitivity that could not be predicted by present measures. Suggestions for maximum protection against unfavorable reactions are as follows: No hair dye should be used where lesions are present on the scalp; no hair dye should be permitted to get into the eyes, and directions should be followed carefully.

In general, three main types of dyes are available. Vegetable dyes, the most popular of which is henna, are among the safest. Cosmetically speaking, the disadvantages are such that their use is limited.

Metallic salt hair dyes are particularly popular for home use. Although the cosmetic results may not be entirely satisfactory, indications at present are that metallic salts are not absorbed through the intact skin. Possibly a serious reaction to a metallic hair dye would result if repeated small amounts were to enter the blood stream over a prolonged period through scalp lesions, through careless oral ingestion or through the mucous membranes. No report is available that establishes a metallic salt hair dye as the cause of metallic salt poisoning.

The aniline type of hair dye is probably the most effective and is also the greatest potential health hazard. Among the most extensively used are paraphenylenediamine and paratoluylenediamine. The Food, Drug and Cosmetic Act of 1938 prohibits the use of any of these dyes in eye make-up, because of serious reactions which resulted prior to that time from their use in eyelash dyes. Furthermore, these dyes are relatively frequent sensitizers, and a caution statement on the labeling to this effect is required by the foregoing law. In addition, directions must be included for a skin test to be executed before each and every application of the dye.

Another type of dye, which is not so commonly used, is the sulfonated azo type dye. Indications are that these may be safer than other coal tar dyes, but several applications are usually necessary to obtain the shade designated.

While certain hazards obviously exist in the use of hair dyes, the number of reported cases of reactions is small in relation to the number of persons who use hair dyes, rinses and other hair coloring agents regularly. Reactions can be kept to a minimum by strict adherence to directions and general precautionary measures.

TREATMENT OF CANCER OF OVARY

To the Editor:—*I removed a 2,240 Gm. ovarian tumor with a pathological diagnosis of papillary pseudomucinous adenocarcinoma of the ovary, grade 2. I also did a complete cleanout of the patient's pelvis. Numerous seedings were present over the peritoneum. The stitches were removed, and x-ray therapy was begun a day later. Would you advise further palliative therapy in the form of testosterone proprionate? If so please outline dosage, frequency and duration. When should this therapy be started?*

W. J. Hill Jr., M.D., Shreveport, La.

Answer.—Total removal of the uterus, tubes, ovaries and omentum, with excision of all implants followed by deep therapy is the accepted treatment for this type of malignancy. There have been no reports of successful therapy with the use of testosterone propionate. If it were to be utilized, it should be given in doses used for the effective treatment of metastatic breast cancer, namely, 50 mg. three times a week for a total dose of at least 1,200 mg. If following this there has been improvement, maintenance therapy should be continued indefinitely. The treatment, if employed, should be begun at once.

WHOOPING COUGH VACCINE AND ENCEPHALITIS

To the Editor:—*Recent reports indicate that some few children may get encephalitis following the injection of whooping cough vaccine as a separate injection or mixed with either tetanus or diphtheria. I have been unable to find any such reports. Do you know of any such cases?*

W. Price Killingsworth, M.D., Port Arthur, Texas.

Answer.—Among the 15 cases of encephalitis following the injection of pertussis vaccine reported by Byers and Moll (*Pediatrics* **1**:437 [April] 1948) the vaccine combined with diphtheria or tetanus toxoid, or both, was administered in three. It should be remembered that most of the cases in the foregoing series occurred in a 10 year period when triple antigens were not available. More recently Anderson and Morris (*Lancet* **1**:537 [March 25] 1950) and Vahrman (*Brit. M. J.* **2**:608 [Sept. 9] 1950) have reported encephalitis after injections of combined diphtheria and pertussis antigens. However, there seems to have been no instances recorded lately when triple antigens were used.

FORMULAS FOR DETERMINING BASAL METABOLIC RATE

To the Editor:—*My records include two formulas which have been employed in determining the approximate basal metabolism of a person from his blood pressure and pulse rate: BMR = (PP + PR) — 111; BMR = 0.683(PR + 0.9 PP) — 71.5. Could you please advise where these formulas first appeared and what, if any, practical value might be placed on them?*

I. Jacques Yetwin, M.D., Springfield, Mass.

Answer.—The formula BMR = 0.683 (PR + 0.9 PP) — 71.5 is one suggested by Read (*J. A. M. A.* **78**:1887 [June 17] 1922; *Arch. Int. Med.* **34**:553, 1924).

The formula BMR = (PP + PR) — 111 is a modification of the Read formula made by Gale and Gale (*Lancet* **1**:1287 [June 13] 1931).

An excellent criticism of these formulas has been given by Eugene Du Bois (Basal Metabolism in Health and Disease, ed. 3, Philadelphia, Lea & Febiger, 1936, pp. 340-342).

CHRONIC SINUS INFECTION

To the Editor:—*What is the consensus among specialists in diseases of the nose, throat and ear and in roentgen therapy concerning treatment of chronic sinus infection and/or lymphoid hyperplasia of the nose and throat in children aged 3 months to 8 years? In the hands of a competent roentgenologist is there danger of damage to the eye and the optic nerve, to the ear and the eighth nerve?*

J. Reginald Myers, M.D., Everett, Pa.

Answer.—Roentgen therapy for the conditions mentioned is helpful, and results are often gratifying. When the worker is an expert, damage to the eye and its optic nerve or to the ear and its nerves would be almost impossible. The doses normally used are not such that they can harm these or any other structures in the area.

HIRSUTISM

To the Editor:—*A girl 20 years old, single, has excessive hirsutism of the face and upper lip. Menses are fairly regular (every six weeks). She began menstruating at age 13. Would doses of estrogens 1 mg. of diethylstilbestrol every day for two months, do anything toward removing the excessive hair growth? There is no evidence of ovarian or adrenal tumor.*

Lewis W. Berry, M.D., Chelan, Wash.

Answer.—The problem outlined is a common one and usually very distressing to the afflicted person. The following procedure is suggested:

1. Careful history and physical examination. [illegible] regular intervals, normal development of the breasts and external genitalia, absence of enlargement of the clitoris and absence of change in the voice suggest that a masculinizing tumor is not present.

2. At least three determinations of the 17-ketosteroid excretion in the urine on different days to exclude the possibility of excessive production of androgen.

3. If no masculinizing tumor is present, the administration of estrogen in large doses will inhibit the growth of hair but will not cause it to fall out.

4. It is probably desirable to remove the hair on the face by electrolysis.

ANESTHESIA AND QUININE IN OBSTETRICS

To the Editor:—*In* The Journal *of Feb. 17, 1951 (page 530) are two queries on obstetric problems, "Saddle Block Anesthesia in Obstetrics" and "Use of Quinine During Pregnancy." I disagree with some of the statements in the answers. 1. Regarding the use of saddle block anesthesia in obstetrics, the statement is made that this type of anesthesia "merits an important position in the management of premature labor, toxemia and certain instrumental deliveries—particularly the posterior position of the occiput—insuring against anoxic depression of the infant from general anesthetics." While agreeing with the other points I disagree with the recommendation that it be used in posterior positions of the occiput. For various reasons its use in these positions is found to further complicate the picture, except when the cervix is fully dilated and the head is well down. This has been observed repeatedly by my associates and me, both in private practice and in our service at Charity Hospital, where the method was first employed by Adriani and his associates of the department of anesthesia. 2. Regarding the use of quinine in the treatment of malaria during pregnancy and lactation, we have not hesitated to use it by mouth in the usual dosage. There is no advantage in its use by injection. I doubt that it has any stimulating effect on the pregnant uterus; this view is supported by numerous pharmacologists. Its employment as an agent to induce labor has been discontinued because it has been found to be of no value. In larger doses, it may cause the death of the fetus in utero. In the doses used in the treatment of malaria, it might affect the hearing apparatus of the fetus but has not, as far as is known, produced fatal effects. For these reasons, efficient substitutes for quinine are advisable in the treatment of malaria in the pregnant woman.*

Professor of Obstetrics, Emeritus,
Tulane University,
New Orleans.

VISUAL ACUITY OF A TEACHER

To the Editor:—*In the answer in* The Journal *(March 10, 1951, page 774) to the query on "Visual Acuity of a Teacher" an erroneous recommendation is made, to the effect that a teacher with low visual acuity would be especially well adapted for teaching sight-saving classes. Having observed the work of many teachers of children with partial sight all over the United States, I am convinced that such a teacher would be at a great disadvantage. Although many school books are available in 18 point type, the variety of books so [illegible] is limited. It is necessary in every class of children with partial sight that the teacher secure other books and publications, including newspapers and news magazines, printed in [illegible] 8 point and even smaller type, which are of [illegible] interest in education. The teacher of children with partial sight, therefore, needs particularly good vision to interpret to the children material that they cannot read. Often the teacher types the most significant of such material on a bulletin board typewriter so that it may be available to the children. This she would not be able to do if she were seriously handicapped. Persons with such handicaps should not be [illegible] consider themselves "especially well adapted" for teaching children with partial sight.*

EARLY DETECTION OF BRONCHIOGENIC CARCINOMA

Donald L. Paulson, M.D.
and
Robert R. Shaw, M.D., Dallas, Tex.

The over-all salvage rate for bronchiogenic carcinoma remains disappointingly low in spite of advances in its surgical treatment. Pulmonary resections for this neoplasm are now common and can be performed with low morbidity and mortality rates. The disappointing fact is that although surgical removal offers the best treatment available today, it cannot be applied to two thirds of the patients with bronchiogenic carcinoma because the cancer is so far advanced when first seen by the surgeon. The medical profession, having developed an acceptable treatment for cancer of the lung, is now confronted with the problem of its earlier detection in order to make its treatment more effective for the over-all group of persons with this disease.

Recently, we have surveyed our experience during the past three and one-half years with 362 patients having bronchiogenic carcinoma. Of this group, 180, or 50 per cent, were considered clinically inoperable when first seen because the cancer was so far advanced. Of the remaining 182 patients operated on, the lesion was found to be inoperable at exploration in 75, or 20 per cent of the total number. It was possible for us to resect the lesion in 107 patients, or only 30 per cent of the original number. In approximately one half of these, the resection was classified as palliative and not curative because of the extent of the lesion.

The patient, the physician and the natural history of the cancer itself all share in the responsibility for this state of affairs. A review of the histories of the patients in this series revealed that there was an average elapsed time of five months from the onset of symptoms until the patient sought medical advice. This delay is attributed to the casual attitude of the patient toward his symptoms and the failure of the cancer itself to produce any or, as far as the patient is concerned, only trivial symptoms during the initial few months. Of greater significance, however, is that another six month period, on the average, was consumed before the correct diagnosis was made or suspected after the patient presented himself to the physician. A total of 11 months was lost on the average before suitable treatment could be applied. It is not surprising, therefore, that only 30 per cent were resectable.

Through education of the public, with particular reference to the significance of a cough and the necessity for periodic roentgenograms of the chest, the delay on the patients' part may be reduced but its elimination will be difficult. The six months' delay on the part of the physician, however, constitutes a real challenge to all of us, which we must accept and answer.

What are the reasons for this six months' delay in the physician's suspecting or making a diagnosis of bronchiogenic carcinoma? It cannot be attributed to a lack of concern or conscience on the part of the physician in most instances. In almost all cases it is due to an error in the original diagnosis and the absence of a characteristic clinical pattern early in the disease. The symptoms of a bronchiogenic neoplasm are largely those of infection, common to almost any lung disease. Its onset is insidious, and its manifestations are not usually clearly indicative of the underlying cause until late in its natural course. For this reason, the physician is frequently fooled early in the course of the disease and makes an erroneous diagnosis of asthma, bronchitis, virus pneumonia, unresolved pneumonia, tuberculosis or a fungus disease.

Attitudes of mind may contribute to the delay in diagnosis. The medical profession as a whole does not fully appreciate the prevalence of bronchiogenic carcinoma. This tumor by apparent and probable actual increase is now the commonest cancer as a cause of death in men. The greatest number of cases occur between the ages of 40 and 60 years. If this prevalence were fully appreciated, bronchiogenic carcinoma would be high on the list of possibilities in the differential diagnosis for any pulmonary or bronchial lesion in a man over the age of 40. Suspicion alone of the possibility of this lesion leads to an earlier accurate diagnosis. Also the physician is naturally reluctant to make a diagnosis of such a serious tumor with all it entails, and he tends to favor a less serious condition which can be treated by simpler meas-

---

Read before the Section on Diseases of the Chest at the Ninety-Ninth Annual Session of the American Medical Association, San Francisco, June 29, 1950.

ures and carries a better prognosis. This reluctance should give way to an eagerness on the part of the physician to detect these neoplasms early, when a cure is still possible.

Virus or atypical pneumonia and unresolved pneumonia are two of the commonest erroneous diagnoses, which contribute to the delay in the discovery of bronchiogenic carcinoma. The diagnosis of virus or atypical pneumonia can be made only by inference; there is no positive diagnostic test for this condition. If a diagnosis of virus or atypical pneumonia is made and the lesion within the chest does not clear promptly, the physician must consider the possibility of another cause such as bronchiogenic carcinoma. Virus pneumonia accounted for over one half of the errors in diagnosis in patients having bronchiogenic carcinoma who were finally referred to us for treatment.

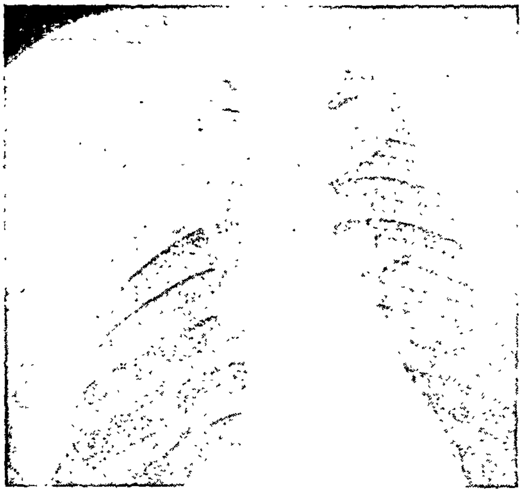

Fig. 1.—Roentgenogram of the chest taken in January 1949, revealing an area of obstructive pneumonitis in the right upper lobe.

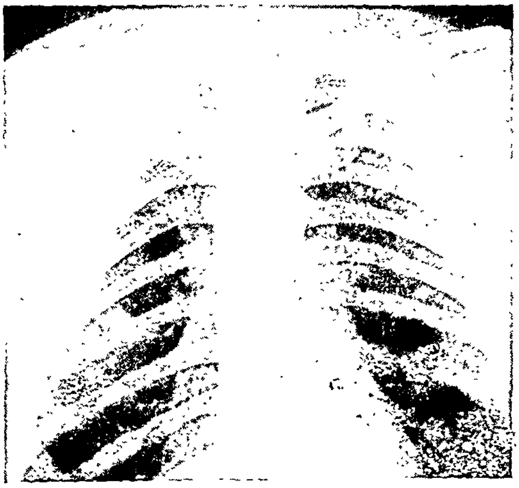

Fig. 2.—Roentgenogram of the chest of the same patient as in figure 1 taken in May 1949, revealing clearance of the obstructive pneumonitis by means of antibiotic therapy. A carcinoma is still present but not visualized.

Unresolved pneumonia is a diagnosis that should be discarded in view of an improved understanding of pulmonary lesions. Unfortunately it is used as a description of a lesion of unknown origin visualized in the roentgenogram. It infers a benign condition which should be treated conservatively. Yet pathologists do not recognize it as an entity and use the term fibroid pneumonitis to describe such a lesion. Fibroid pneumonitis usually results from an inflammatory process distal to a blocked bronchus, and the block may be due to a neoplasm. A true pneumonia will resolve promptly, and if resolution does not occur, another cause in differential diagnosis must be considered. Bronchiogenic carcinoma, bronchiectasis, abscess and tuberculosis are the common causes of an obstructive (fibroid) pneumonitis. In a man over the age of 40, the lesion must be considered due to carcinoma until proved otherwise. The proof may readily require surgical exploration.

The third factor influencing the delay in the diagnosis of bronchiogenic carcinoma is its natural history or pathologic course. Unfortunately there is a large group of patients in whom it is impossible for one to make the diagnosis at a time when surgery is still applicable. As a result of our study of 362 patients, we found that in 25 per cent the initial complaint that prompted the patient to seek medical advice was one indicating inoperability, such as headache due to a cerebral metastasis, loss of voice due to involvement of the recurrent laryngeal nerve, painless pleural effusion, dysphagia due to involvement of the esophagus, involvement of distant organs as the peritoneum, or subcutaneous metastases due to generalized spread of the cancer. The insidious course and the paucity of symptoms early in this group constitute an insoluble problem in diagnosis except by routine, periodic, roentgenographic examination of the chest. Twenty per cent of our patients had an undifferentiated bronchiogenic carcinoma. This cell type is highly malignant, rapidly invasive and tends to metastasize early. Only 8 per cent of the resections were made up of undifferentiated carcinomas, and only one of these patients has survived over 12 months. It is widely recognized that an undifferentiated carcinoma is practically a sign of inoperability in itself. If 25 per cent of the patients in whom the initial complaint indicated inoperability are added to the 20 per cent who have an undifferentiated type of carcinoma and allowance is made for some overlapping in the two groups, we estimate that roughly 40 per cent of patients having bronchiogenic carcinoma are inoperable when first seen by their physician. This leaves about 60

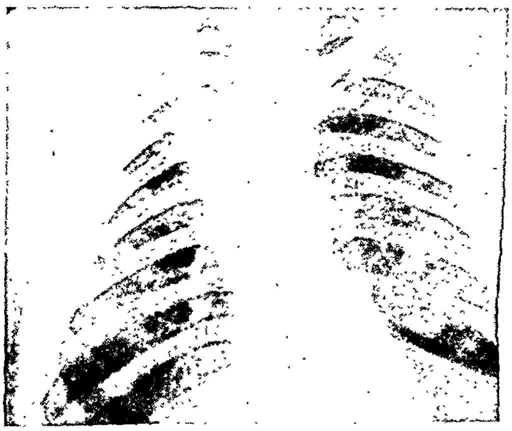

Fig. 3.—Roentgenogram of the chest of the same patient as in figures 1 and 2 taken in September 1949, revealing an atelectasis of a portion of the right upper lobe. Surgery at this time revealed a bronchiogenic carcinoma.

per cent, or two thirds, in whom early diagnosis may make a cure possible. Today we are getting the opportunity in only 30 per cent or less than one third.

SYMPTOMATOLOGY

Bronchiogenic carcinoma passes through early a silent phase of variable duration, depending on its growth potential. It produces symptoms only by breaking through the bronchial mucosa, which thereby produces an irritating cough, or by blocking the bronchus, with the resultant obstructive pneumonitis in the area of lung supplied by that bronchus. The cough is productive of mucoid, blood-streaked or rusty sputum. In many instances the first symptoms are common to the less serious respiratory disorders and consequently receive little serious attention. As time goes on, these symptoms become more severe, and new ones are added. Cough, pain, weight loss, hemoptysis, dyspnea, fever, recurrent respiratory infections, wheezing and hoarseness are the symptoms that develop later in the course of the disease. Cough is the most constant symptom and usually persists throughout the course of the disease.

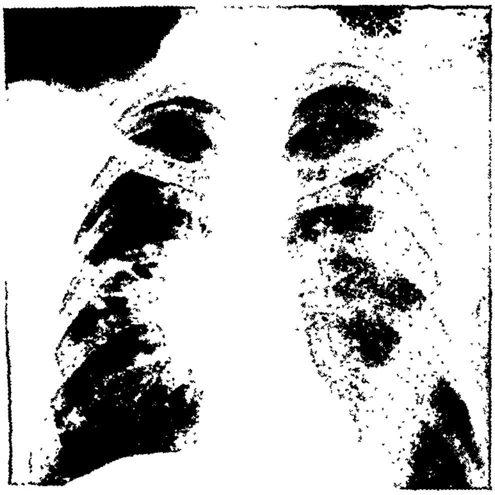

Fig. 4.—Roentgenogram of the chest illustrating a lobulated unilateral mass with a surrounding pneumonitis typical of a bronchiogenic carcinoma.

Wheeze and hemoptysis usually occur early and are due to encroachment on the bronchial lumen or erosion of the mucosa. Pain is actually a late symptom unless it be due to the accompanying pneumonitis. The pain of the carcinoma itself is caused by pleural, chest wall or mediastinal involvement, all of which portend an already far advanced lesion. Weight loss, dyspnea, fever and hoarseness all come late. There is no characteristic symptomatic pattern for bronchiogenic carcinoma until late. We must raise our indices of suspicion to detect this lesion early without the advantage or benefit of a characteristic symptomatic pattern.

ROENTGENOGRAPHIC EXAMINATION

Roentgenographic examination of the chest is the most valuable single method available for the early detection of bronchiogenic carcinoma. The neoplasm itself may not be visualized usually, but its effects are seen as areas of obstructive pneumonitis (figs. 1, 2 and 3). Lesions within the hilum growing outside the bronchial lumen may appear as a lobulated unilateral mass. The shadow cast on the roentgenogram is composed of tumor, lymph nodes and the pneumonitis in the adjoining lung tissue (fig. 4). A tumor which grows mainly into and around the bronchus may produce collapse of an entire lung, a lobe or a segment, with retraction of the mediastinum and the diaphragm (fig. 5). Earlier the affected lung, lobe or segment may be emphysematous because of trapped air. An early roentgenographic sign of bronchiogenic carcinoma is a localized area of emphysema on expiration.

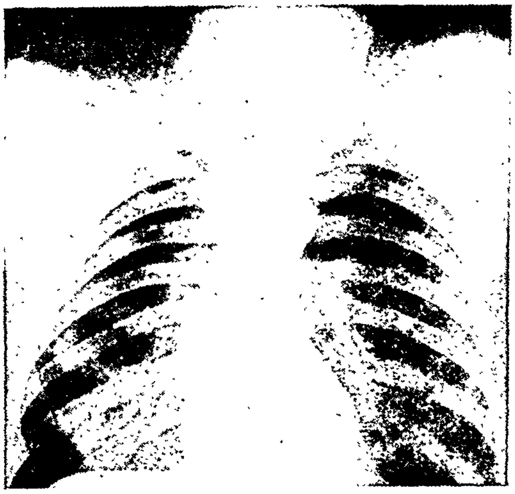

Fig. 5.—Roentgenogram illustrating segmental atelectasis of the right lower lobe due to bronchiogenic carcinoma.

Tumors arising in smaller bronchi rapidly become obstructive and early give rise to a circumscribed, round or oval shadow in the roentgenogram. It must be differentiated from the tuberculoma, coccidioidal granuloma, cyst and abscess (fig. 6). Usually this is impossible except by exploratory thoracotomy. Not infrequently this type of lesion undergoes cavitation due to central necrosis or the associated pneumonitis (fig. 7). In such instances an erroneous diagnosis of lung abscess may be made by the roentgenologist.

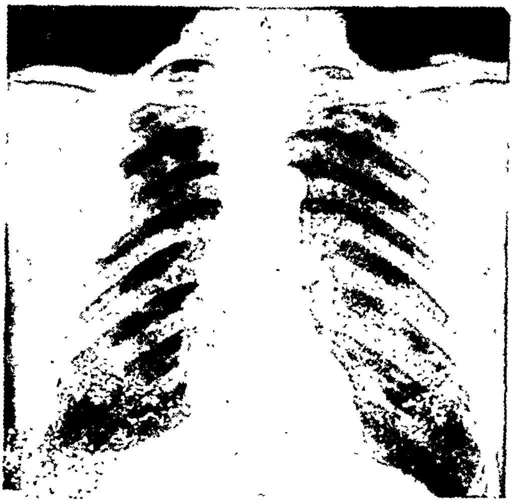

Fig. 6.—Roentgenogram illustrating peripherally located bronchiogenic carcinoma of the right upper lobe.

Tumors arising in the extreme periphery of the lung may not cast a shadow on the roentgenogram. Four cases in this series were of this type. The initial symptom was pain. Surgical exploration revealed a plaque of carcinoma involving visceral and parietal pleura. A peripheral opacity separate from the underlying lung may be visualized in the roentgenogram. Tumors of this type in the apex are referred to as superior sulcus tumors. They may occur on any surface of the lung. Pleural effusion may be the first sign of a peripherally located tumor.

Both posteroanterior and lateral roentgenograms should be utilized in any examination of the chest, because there are large areas in the lung fields not visualized by the ordinary posteroanterior roentgenogram alone. Small neoplasms may be obscured by the heart shadow, the arch of the aorta or the pulmonary vessels. A lateral roentgenogram will visualize lesions in these obscure areas. Bronchography may be of value in revealing an abrupt bronchial block. Laminography likewise is of great value in showing bronchial blocks or tumors in the above mentioned obscure areas.

One must always be mindful of the fact that roentgenograms reveal shadows only, and that there is nothing diagnostic of the type of shadow produced by a bronchiogenic carcinoma. By experience we have learned to make a roentgen diagnosis on the basis of percentage possibilities. Very often actual surgical exploration is necessary for the precise determination of the nature of the lesion. Interpretation of the shadow in the roentgenogram must be made in correlation with the history, the physical signs, laboratory findings and observations made at bronchoscopy.

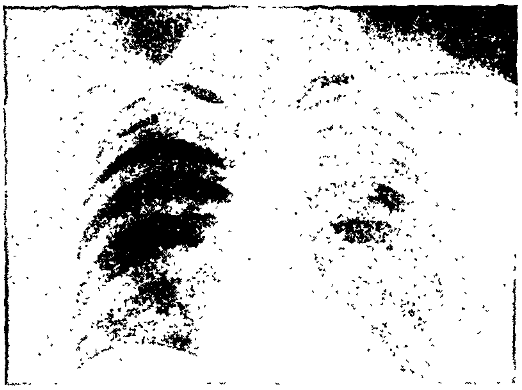

Fig. 7.—Roentgenogram illustrating cavitary carcinoma of the left upper lobe.

SPECIFIC METHODS OF DIAGNOSIS

Of the specific methods of diagnosis in bronchiogenic carcinoma, bronchoscopy is the most valuable. By this procedure, one is able to visualize the bronchial tree, obtain tissue from the lesion for study by the pathologist and collect bronchial secretions or washings for cytologic study. It must be remembered that all parts of the bronchial tree are not visible bronchoscopically. This means that carcinomas arising in the smaller bronchi are not accessible to either visualization or biopsy. Bronchial secretions or bronchial washings may be obtained from the suspected lobe. Malignant cells which have exfoliated from the neoplasm may be found in the material thus aspirated. Examination of the patient's sputum may likewise reveal the presence of malignant cells. In view of the limitations of bronchoscopy in the examination of the tracheobronchial tree, it must be remembered that a negative finding in bronchoscopy or failure to find malignancy in either a biopsy or in bronchial secretions or washings does not rule out carcinoma. In other words, a positive finding is of great significance but a negative finding does not rule out the possibility of carcinoma.

Lung aspiration or needle biopsy, although advocated by some, is, in our opinion, hazardous and superfluous. If one suspects carcinoma, exploratory thoracotomy should be done anyway, regardless of the findings by needle biopsy. The dangers of needle biopsy are air embolism, pneumothorax, spread of the carcinoma along the needle tract, tumor embolism and empyema. In our opinion the use of aspiration biopsy should be limited to those patients in whom exploratory thoracotomy is contraindicated and a proved diagnosis is desirable.

Another specific method of diagnosis in bronchiogenic carcinoma is exploratory thoracotomy. The risk of exploratory thoracotomy is very low, being no greater than the risk of exploratory laparotomy. It so happens that most of the lesions that will be confused with bronchiogenic carcinoma are amenable to and should be treated by resection. At the time of the exploratory thoracotomy, biopsy of malignant tissue in the hilar lymph nodes or at the extreme periphery of the lung may be performed. If the lesion is inaccessible for biopsy, either a segmental resection or a lobectomy should be done, the tissue examined by the pathologist immediately and a report given the surgeon. The appropriate procedure may then be carried out.

After completion of a careful history and physical examination, a roentgenographic examination of the chest and bronchoscopic examination for an indeterminate lesion in a man over the age of 40, exploratory thoracotomy is mandatory and should be accomplished without delay. The passage of time is inimical to the patient's best interest. Observation of the patient for a period of time is extremely unwise. If the lesion remains unchanged, one still cannot rule out the possibility of bronchiogenic carcinoma. If the lesion increases in size or a distant metastasis becomes evident, one has been guilty of loss of valuable time for the patient. The question the surgeon should ask himself in regard to all indeterminate chest lesions is this: Can I honestly tell the patient this is not a carcinoma? If he cannot, the patient should be advised to have an immediate thoracotomy.

EARLY DIAGNOSIS OF BRONCHIOGENIC CARCINOMA

The early diagnosis of bronchiogenic carcinoma is difficult if one demands absolute proof of the presence of this lesion for the diagnosis. However, if one's index of suspicion is maintained at a high level, the early detection of bronchiogenic carcinoma is not impossible. In about two thirds of the patients having this condition, early diagnosis is possible if one keeps in mind the prevalence of this type of cancer, its natural history and its symptomatology. Appropriate studies, including roentgenography, bronchoscopy and exploratory thoracotomy, are indicated to make the diagnosis.

Because of the natural course of bronchiogenic carcinoma, there is an early silent phase in which a lesion can be detected only by routine, periodic roentgenograms of the chest, as suggested by Overholt and Schmidt in 1949.[1] As a result of surveys for tuberculosis, as many as 10 asymptomatic carcinomas per 100,000 roentgenograms have been found. Mass surveys have been extremely valuable in case finding for tuberculosis and have reduced the incidence of far advanced cases by the discovery of minimal cases. In the future it may be possible to do the same for bronchiogenic carcinoma. In the meantime, we can improve our detection of those cases we are seeing every day by making an earlier diagnosis.

SUMMARY

The over-all salvage rate for bronchiogenic carcinoma remains disappointingly low in spite of advances in its surgical treatment. Pulmonary resection could be applied to only 107, or 30 per cent, of 362 patients having bronchiogenic carcinoma seen by us during the past three and one-half years. The patient, the physician and the natural course of the cancer itself are responsible for the late diagnosis of bronchiogenic carcinoma. A plea for the early detection of this lesion is made, and the symptomatology, the roentgenographic findings and specific methods of diagnosis are reviewed.

3810-3812 Swiss Avenue.

ABSTRACT OF DISCUSSION

Dr. John C. Jones, Los Angeles: That a longer delay exists between the time the patient first consults his physician until the true diagnosis is made than between the time from the initial onset of symptoms until the patient consults his physician in regard to these symptoms is a shocking reality. In Dr. Paulson's series there was an average delay of five months from the onset of symptoms until the patient consulted his physician, and then there was another average delay of six more months after the patient went to his physician before the correct diagnosis was made. I reported a series of patients with carcinoma of the lung four years ago, and I was more encouraged about the outlook of early diagnosis of bronchogenic carcinoma at that time than I am now. In our group of cases, if the patients who are diagnosed by mass roentgenogram surveys are excluded, I believe there is a longer delay from the time the patient consults the physician until a correct diagnosis is made than there used to be five years ago. I tried to analyze these cases, and the only conclusion that I came to is that when there were only the sulfonamides, we physicians had a few drugs to use and the diagnosis was eventually made. Now we have too many drugs. Therefore, we start with the sulfonamides; then the patient is put through the whole gamut of antibiotics and he does not improve. Discouraged, he goes to another physician, who treats him with courses of the various antibiotics all over again. There are just too many different preparations, and the patient is subjected to a lot of therapy and is not exposed to any diagnostic acumen. There is going to be a limit to the technical improvements of pneumonectomy that a surgeon can contribute. The incidence of complications is low. Four years ago I reported a series of pneumonectomies in which the mortality was 4 per cent. The improvement in the results of the treatment of carcinoma of lung must come as the result of early diagnosis and mass roentgenogram surveys. Dr. Paulson stated that 30 per cent of his patients were operable, but half of these were patients in whom he was sure at the time of the operation that he was doing only a palliative procedure. Actually then he was offering a cure to 15 per cent, and not 30 per cent, of the operated patients. I do not believe the surgeon should hesitate, if he cannot find lymph nodes either peripheral or central, to do a so-called lobectomy biopsy. Certainly an older patient with a peripheral lung carcinoma and fibrotic and emphysematous changes may withstand a lobectomy without complication and dyspnea, and furthermore the end result of a cure may in a whole series of patients be just as good as, if not better than a pneumonectomy, which is hazardous in this type of patient. Then too, if it turns out that the patient has a benign lesion, only the lobe has been resected, and the patient has not been incapacitated. He has been given the protection of an earlier and an accurate diagnosis and with no sacrifice. If thoracotomy is done in patients who are hopelessly inoperable, then the physicians who are to care for these patients afterward are going to be discouraged with exploratory thoracotomy. If a patient is hopelessly inoperable, then that patient is not so well off or so comfortable as he was before the procedure. Such indiscriminate practice contributes only to the discouragement of the patient and the physician who treats the patient until the latter dies.

Dr. Donald L. Paulson, Dallas, Tex.: I agree with Dr. Jones about exploratory thoracotomy and obviously hopeless lesions. We are coming to the position more and more that if we are sure that a cancer is of the undifferentiated small cell type, we most usually should not offer surgery to the patient, because our results are poor from the standpoint of resection in that group.

THE HEREDITY OF EPILEPSY AS TOLD BY RELATIVES AND TWINS

William G. Lennox, M.D., Boston

"Can there be marriage and children"? This is one of the most urgent questions propounded by the epileptic and his relatives, and one of the most difficult to answer. Answers given by doctors differ radically. One will deny and the next will affirm the importance of heredity. In giving advice, many forget that the problem refers to a person possessed of not just one transmissible trait, but of many. A condition that argues against marriage and children may be neutralized, or even outweighed, by other conditions that favor marriage. These will be considered after the testimony of relatives has been reviewed.

OPINIONS IN THE PAST

For the most part, doctors and laymen alike have recognized a transmissible quality. Hippocrates called epilepsy a familial disease. Burton's "Anatomy of Melancholy" states that the ancient Scots "instantly gelded" any man with falling sickness and if a woman "were found to be with child, she with her brood were buried alive." The laws (happily moribund) of 14 of our states go one step further—forbidding marriage of the epileptic, and even threatening fine or imprisonment for any who assist.

In the important subject of genetics, man plays second fiddle to the fruit fly. In spite of the importance of the question of heredity of epilepsy to both patients and the public, published data on the subject have, in general, been conflicting or unconvincing. References and background information will be found in certain previous pub-

lications.[1] At present, I am concerned with evidence garnered from two groups: first, the 20,000 near relatives of approximately 4,000 epileptic patients, and, second, 122 twin pairs affected by seizures.

METHODS OF STUDY

One must first consider the inaccuracies that attend a statistical study of the symptom complex called epilepsy. There are uncertainties of definition and of differential diagnosis. In addition, the family and other history must be obtained about an illness which many persons consider a deep disgrace. In order to study the relative influence of genetic and acquired factors in epilepsy, one must separate patients into those with and those without evidence of brain damage that existed prior to the first seizure. Evidence includes the past history, the pattern of the convulsive phenomena, neurological examination and the findings in certain tests, such as the pneumoencephalographic and the electroencephalographic. Decision is complicated by the fact that the observed brain damage may be a result, rather than a cause, of the epilepsy. Because evidence both of a brain lesion and of a significant family history may be hidden, the assignment of cause or causes in many cases must be deferred. Some writers employ a name idiopathic or cryptogenic, which sounds meaningful but says only, "I don't know." The terms "cause unassigned" seems preferable. Again, the forces of nature and nurture (or heredity and environment) are not fixed and are not mutually exclusive. Thus, the seizures of many patients will be the result of both predisposition and brain injury. Furthermore, the predisposition will be the minor factor in one patient and the major factor in another. Thus, among 2,053 patients seen in the office (three-fourths) or in the clinic (one-fourth), the proportionate representation of causes was as follows: a family history of epilepsy or migraine, 43 per cent; evidence of cerebral damage that antedated the first seizure, 27 per cent (with overlapping of these two conditions in 11 per cent) and cause as yet unassigned, 41 per cent. The present report is an effort to reduce the size of this large, unassigned (idiopathic) group.

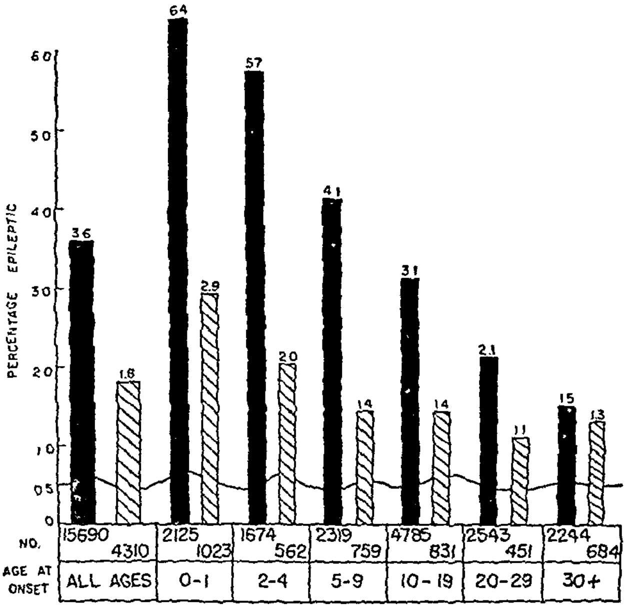

Fig. 1.—Incidence of epilepsy among 20,000 near relatives with reference to antecedent brain damage and age at onset of the seizures. The number of relatives and the age at the time of the first seizure are indicated at the bottom of the chart. The scale at the left gives the percentage of relatives who have had seizures. *The solid columns represent the patients* without antecedent brain damage, and the hatched columns, those with evidence of such damage. The wavy line near the bottom represents the portion of draftees (0.515 per cent) rejected because of epilepsy during the World War I. The waviness of the line suggests the possible inaccuracy of this figure.

DATA FROM FAMILY TREES

My colleagues and I have studied the family histories of 4,231 patients seen in the office or the clinic. Data for approximately one third of these were supplied by certain members of the American Neurological Association. Because the symptom of seizures is scattered widely throughout the population, every family tree, if examined twig by twig, would display one or more instances of this disorder. In addition to counting the number of affected families, we determined the number of affected persons in the population that immediately surrounded the patient—his parents, siblings and children. Even in this compact group, diagnoses are often in doubt. In these tabulations, a person subject to seizures that were not considered syncope, hysteria, carotid sinus syndrome or the result of defective metabolism was counted as epileptic without regard to precipitating conditions, such as fever, excessive use of alcohol or extreme emotion. The question whether one or two seizures are necessary for a diagnosis was compromised by accepting one seizure in one-half and two seizures in the remaining half of the total group.

Epileptic patients were divided into two groups—those with and those without evidence of a neuropathologic condition that antedated the first seizure. Of these patients, 22.9 per cent gave evidence of antecedent gross brain lesions (with or without a significant family history) and were assigned to the group having "symptomatic," or acquired, epilepsy. This left 77.1 per cent in the group without prior damage to the brain, composed of the patients with "essential" (genetic) epilepsy and the patients with unassigned cause. The results are displayed in the two left-hand bars of figure 1.

The incidence of epilepsy among all near relatives was 3.2 per cent. In the group without brain damage it with 3.6 per cent. For the group with brain damage, the incidence was 1.8 per cent. Thus, judging from the number of epileptic relatives, the genetic influence in the group with symptomatic epilepsy was one-half that present in the group with essential epilepsy.

For data regarding the incidence of a condition to have meaning, there must be comparison with the distribution of this condition throughout the general population. In the two world wars, approximately 0.5 per cent (1 in 200) of draftees were excluded because of epilepsy.[2] Persons confined to institutions and children, with their high seizure rate, were not involved—moreover, many men failed to report seizures that might be quiescent, and the screening of others was extremely coarse. These conditions would tend to depress the incidence below its true general level. The wavy line in figure 1 expresses the uncertainty regarding the accuracy of the draft values. In the group of patients with brain intact, the incidence is 7.2 times that reported in the draft. In the group with damage to the brain, it is 3.6 times as great. If the two groups were mutually exclusive and epilepsy in the group with brain damage were due solely to the acquired condition, then affected relatives of this group should not exceed the number in the general population. A threefold increase simply reflects the fact that in many patients both genetic and acquired conditions are at work. The physician whose patient has onset of epilepsy after a head injury cannot say that the chances of epileptic offsprings are nil, nor can the physician who sees a family tree bedecked with epilepsy or migraine close his mind to the possibility of brain tumor.

C., Medical Statistics, Aug. 1, 1943.

Age at Onset.—Conditions that are predominantly genetic tend to manifest themselves early in life. If persons whose seizures started in early childhood have an unusually large number of epileptic relatives, this fact strengthens the evidence for heredity. This number should be disproportionately large also for the group without prior brain damage. The slender columns of figure 1 display the results of tabulations designed to test these points. The age at onset was taken as that at the first seizure, even if this occurred in the first months of life and recurrent attacks did not start until years later. In the group with undamaged brain, if epilepsy began in infancy, 6.4 per cent of relatives were affected, against only one-fourth that number (1.5 per cent) if epilepsy started after the age of 30. Corresponding percentages for the group with brain damage are 2.9 and 1.3 per cent, respectively. The fact that this symptomatic group shows some downward progression as the age at onset increases points again to a genetic influence at work, even in the presence of an apparently sufficient acquired cause. (The objection might be raised that the younger the patient, the greater the parental history of seizures, since parents themselves might be the informants. On the other hand, the older the patient, the more time there would be for epilepsy to have developed in siblings, and perhaps in children. Moreover, the factor of adequate information should affect the essential and the symptomatic group equally.)

EVIDENCE GAINED FROM TWINS

The statistical data already presented suffer from the uncertain mixture of genetic and acquired elements. One-egg (monozygotic, similar, identical) twins offer the great advantage that the element of heredity is the same for the two persons (the co-twins) that compose the pair. Hence, characteristics that are hereditary (such as the color of hair and eyes, the height and weight, the blood type and the electroencephalographic pattern [3]) are the same. Consequently, to the degree that seizures or the tendency to them is genetically derived, both co-twins of a one-egg pair will be epileptic or have that tendency. On the other hand, if but one has seizures and these followed some acquired lesion of the brain, the epilepsy of that person presumably is acquired. The family histories of the twins of this study support this presumption. Of the 167 near relatives of one-egg twins without evidence of brain damage prior to the onset of seizures, 6.6 per cent were epileptic, against none of the 103 relatives of the one-egg twins with evidence of a prior pathologic state.

Two studies dealing with series of epileptic twins have been published, the one by Rosanoff, Handy and Rosanoff [4] and the other by Conrad.[5] Although the series were of satisfying size, namely, 107 and 157 pairs of twins respectively, the cases apparently were gathered by means of reports from institutions, without personal examination, and, of course, the studies did not include the use of the electroencephalograph.

The series of 122 pairs of twins here reported has been collected during the past 15 years with the assistance of associates, especially Dr. and Mrs. F. A. Gibbs. Patients were encountered in clinic or in private practice, many of them through referring physicians in various sections of the country. Of the 122 sets of twins, 13 were not examined personally; of four others, only one co-twin was seen, and electroencephalograms of six pairs were not obtained. Two of the twin pairs had been reported previously by others.[6] The questions of zygosity, often a difficult one, was decided through comparison of the various physical hereditary traits, details of which appear in preceding communications.[7]

Sixty-nine pairs were judged to be derived from one ovum and 53 pairs from two ova. The difficulty of decision is often increased because one set of twins may be more nearly identical than another set, and, more important, an acquired brain injury, derived perhaps from the convulsions themselves, may alter characteristics used in judging identity, such as size, the intelligence of the person and his electroencephalogram. In young children, confusion may arise because the first seizure may have been a febrile convulsion which, though generalized, was followed by hemiparesis and later by focal convulsions.

The following case is illustrative: Bernice and Helen, now 25 years of age, each had a few convulsions at the age of 2 or 3 years—whether febrile or not is unknown. Helen has had none since; she has an intelligence quotient of 135, shows a normal electroencephalogram and has professional training. One of Bernice's babyhood convulsions was followed by hemiparesis, which cleared after several months. Focal seizures have continued to occur and now number several thousand. Her intelligence quotient is 109. Because of the seizures and destructive behavior, directed especially toward her more fortunate twin sister, she has for years been confined to a mental hospital.

Extreme ages of twins were 6 months and 42 years. The percentage of females, especially among the members who were epileptic, was unusually high. The distribution of twins with respect to zygosity, presence or absence of brain damage and chronicity of seizures is shown in the accompanying table. "Transient epilepsy" refers to patients with febrile convulsions only, or not more than two nonfebrile episodes.

CONCORDANCE OF EPILEPSY

The percentages in the last column of the table are presented in figure 2. These results with respect to concordance are in fair agreement with those of Conrad.[5] Corresponding figures, with Conrad's first, are as follows: one-egg twins: brain intact, 86 and 84 per cent; brain damaged, 12 and 17 per cent; two-egg twins: brain intact, 4 and 10 per cent; brain damaged, 0 and 8 per cent. Twins having only febrile convulsions account for the higher concordance in our two-egg series.

Inspection of these results emphasizes what clinicians have long recognized—that heredity and brain abnormality are both important. However, the present data indicate greater spread between all one-egg and all two-egg twins (52 percentage points) than between all uninjured and all injured twins (36 percentage points). This suggests that heredity may be of somewhat greater influence than brain injury in the etiology of seizures.

Cases of Discordance.—Of particular interest are those one-egg twins who have no history of acquired brain damage and yet only one of the twins is epileptic. In the group of 45 one-egg twins, seven such cases were encountered (16 per cent). Thumb nail sketches of them may be given. The family and past histories were noncontributory unless stated otherwise.

Distribution of Seizures Among One Hundred and Twenty-Two Twin Pairs with Reference to Zygosity and Antecedent Pathology of Twins and Chronicity of Seizures

One- or Two-Egg Twins	Antecedent Brain Pathology	No. of Twins	Both with Chronic Seizures No.	Both with Chronic Seizures %	One with Chronic, One with Transient, Seizures No.	One with Chronic, One with Transient, Seizures %	Both with Transient Seizures No.	Both with Transient Seizures %	One with Chronic Epilepsy, One Normal No.	One with Chronic Epilepsy, One Normal %	Both Twins Affected No.	Both Twins Affected %
One-egg	—	45	21	47	9	20	8	18	7	15	38	84
	+	24	1	4	3	13	0	0	20*	83	4	17

* In two pairs, one with transient seizures and one normal.

Ernest and Salvatore C. are 12 years of age. In the past two years Ernest has had three convulsions without known precipitating circumstances. His electroencephalogram is normal; that of his brother is mildly slow because of the greater build-up during overventilation. Each has an intelligence quotient of 68.

Mrs. B. and Mrs. W. are 23 years of age. Mrs. B., during the past four years, has had approximately 15 convulsions, without known precipitant. A paternal grandfather and uncle had convulsions. The electroencephalogram of each co-twin is a bit fast and contains solitary spike-wave complexes, these being more abundant in Mrs. B.'s record.

Robert and Richard R. are 11½ years of age. In the past 18 months Robert has had one convulsion and three psychomotor seizures. The electroencephalogram of each twin is a bit slow. Robert's intelligence quotient exceeds Richard's by 5 points.

John and Joseph R. are 22 years of age. In the past five years John has had approximately 75 convulsions. The electroencephalograms of both are mildly slow without seizure discharges, John's being a bit the slower. John's intelligence quotient is 4 points below Joseph's.

Edward and Peter L., aged 10 years, have a father and maternal grandmother who experienced convulsions as infants. Edward has had approximately 20 convulsions in the past nine years, the first coming within an hour after a trivial fall. The electroencephalogram of each is a bit slow, the build-up with Edward being greater than that of his brother. Edward's verbal intelligence quotient is 182, being 3 points higher than Peter's. Interesting details will be reported by the patients' neurologist, Dr. William Caveness.

Joseph and James F. are 37 years of age. Joseph, during the past 19 years, has had approximately 50 grand mal and 100 psychomotor seizures. As a boy, he was knocked unconscious by a blow on the head. He has had a hysterical hemiparesis. Both co-twins are neurotic and subject to migraine. During most of the 10 years that the patient has been observed, the diagnosis has been in doubt because of the nebulous description of his symptoms. However, since confinement in a state prison, he has had a number of generalized convulsions, as well as psychotic outbursts, which are probably psychomotor seizures. The electroencephalograms of both twins were considered normal until a sleep recording of Joseph showed slow spikes in the temporal areas. His intelligence quotient, 120, was 2 points above James's.

The cases of Karen and Carol Y. are especially interesting. A maternal cousin has epilepsy. Karen, now 12 years old, began at the age of 6 to have the form of petit mal we term petit absence. Attacks recurred dozens of times daily and were recorded on the electroencephalogram. With persistent use of trimethadione (tridione®) the petit absence of Karen disappeared four years ago, and her electroencephalogram, even in sleep, is normal and free of spike and wave complexes. Carol's electroencephalogram was persistently and (for us) provokingly normal until the impetus of sleep evoked the telltale spike-wave complexes of unerupted epilepsy.

Failure of 100 per cent concordance in these one-egg twins with intact brain may find explanation in one of two ways. Four of the seven pairs of twins are 12 years of age or younger, and the normal co-twin may yet experience seizures, or the epileptic co-twin may have experienced some alteration of body or brain metabolism or some neuropathologic lesion without neurologic signs which precipitated seizures. Mystery surrounds the externalization of cerebral dysrhythmia, as in the case of Alice and Arlene D., illustrated in figure 5.

Also requiring explanation are those cases in which both members of two-egg twins have had seizures. Five of the 53 two-egg twin pairs (9 per cent) were in this category.

Robert and Barbara J. are aged 20. The mother has a history of migraine and of possible seizures in youth. Robert has had persistent convulsions and psychomotor seizures for 15 years. In the past two years Barbara has had occasional vaguely described automatisms, and her electroencephalogram displays temporal spiking.

Anthony and Patricia D., aged 7 years, had a maternal aunt who had convulsions as a child. Each twin has had two febrile convulsions, and Anthony, a few petit absences.

Joan and Phillip G., aged 2 years, have had, respectively, 15 and 16 febrile convulsions.

Pauline and Paul D., aged 3 years, have had, respectively, 10 and one febrile convulsions. The mother had febrile convulsions as a child; the father had convulsions in childhood and now has migraine.

John and Rose Marie F., 3 years of age, are the twin children of a woman who is one of identical twins, both epileptic, reported many years ago by Fabing.[6] John and Rose were both injured at birth. John had continued convulsions and was sent to an institution. Rose Marie had them only during the first week of life and has been adopted.

The incidence of 9 per cent among the co-twins is more than twice the incidence of epilepsy (3.4 per cent) among the 8,006 siblings of patients of our series. In three of the five cases, the convulsions that occurred in both co-twins were febrile. Often fugitive, these may not have as great significance as convulsions that occur without this hair trigger means of precipitation.

CONCORDANCE OF TYPES OF SEIZURES

Does heredity in epilepsy involve only the fact of having a seizure of some sort, or does it go a step further and decree what the pattern of abnormal display shall be? If specific patterns are not transmitted, then distribution of the principal seizure types—grand mal, petit mal and psychomotor—should be scattered among one-egg twins much as they are among pairs of unrelated persons of the same age. If, on the other hand, a person's constitution determines the composition of the seizure pattern, then one-egg twins whose brains have not been altered by some acquired condition should display seizures that are similar. We compared the likeness of seizure patterns in uninjured one-egg twins with the pattern in 100 pairs of patients picked at random from the files. The concordance was as follows: Of 19 one-egg twins affected with but one type, both co-twins had a history of either grand mal or petit mal in 100 per cent (random selection, 38 per cent). In pairs with a history of both grand mal and petit mal in one of the co-twins, the concordance was 70 per cent (random selection, 29 per cent). In the six pairs in which there was a history of grand mal and psychomotor seizures, the concordance was 17 per cent (random selection, 16 per cent). For all these specified seizures or combination of seizures there was concordance in 75 per cent (random selection, 31 per cent). The random sampling did not compare persons of the same age. However, the degree of concordance of types of seizures among the twins would seem to overbalance this age factor.

Concordance was noted also for the subgroups of the petit mal triad. If one co-twin experienced petite absence, myoclonic jerks or drop seizures, the other did also. In one pair, the concordance extended to coincidence. In nine of 10 episodes of falling in a faintlike, astatic seizure, the falls of both girls occurred within a minute of time—on two occasions when they were not in the same room. Of 38 one-egg twins without injury of the brain, the epilepsy of both began within a 12 month period in 22, or 58 per cent.

The conclusion that heredity has much to do with the physical phenomena of the fit is inescapable.

CONCORDANCE OF ELECTROENCEPHALOGRAPHIC PATTERNS

A further, and even more searching, question is whether concordance extends to the type of dysrhythmia. This question probes the possibility of discovering a predisposition to seizures. In their earliest report on electroencephalography, Gibbs, Davis and Lennox[8] depicted bursts of high voltage waves unattended by observable clinical phenomena. These they termed "larval" seizures. Such unseen malactivities, like a planet whose position is plotted by astronomers before it is seen, suggests that an abnormal electrical activity of the brain underlies epilepsy, and gross abnormalities in a healthy person with intact brain might represent a transmissible larval epilepsy or predisposition to seizures.

The electroencephalogram represents minutes of time, against the years of a person's past history of seizures. Hence, observation of paroxysmal phenomena on the electroencephalographic recording may depend on chance, on successive tests or on use of methods of activation, such as hyperpnea, sleep or injection of pentylenetetrazole (metrazol®). Thus, Carol Y., mentioned previously, whose identical twin sister had a profusion of petit absence and of dart-dome discharges, had neither of these on routine testing until an electroencephalogram during sleep disclosed the specific dart-dome discharges.

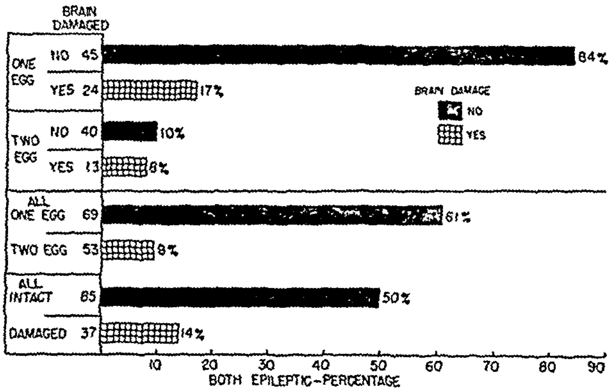

Fig. 2.—Percentage of twin pairs in which both co-twins have a history of seizures. The length of the bars represents the values expressed in the *last column of figure 1. Black* bars are for twins without evidence of brain damage prior to the onset of seizures, and hatched bars are for those with such evidence. Percentage figures are at the ends of the bars, and figures for the number of twin pairs are at the base.

Electroencephalograms were grouped using the classification of the Gibbses.[9] The results of this tabulation are recorded in figure 3. The tracings of some twins were normal, but in the one-egg group 61 pairs displayed some abnormality in at least one of the co-twins. A particular abnormality occurred in both co-twins in 37 (61 per cent) of the 61 one-egg pairs. The corresponding figure for the 40 two-egg twins was only 7 per cent. The agreement was greatest (74 per cent) when there was no high voltage discharge, but simply a dominant rhythm, which was either fast or slow. Among two-egg twins the corresponding concordance was 27 per cent. In the one-egg group, the concordance of the 3 per second spike-wave formation was 66 per cent, that of high voltage slow waves or of spikes, 37 per cent, and that of slow spike-wave complexes, 25 per cent. Of the last three types, none of the two-egg twins displayed concordance of brain wave patterns. The relatively low concordance of the slow spike-wave discharge is due to its association with acquired brain lesions. When the twins with brain damage were eliminated from the calculation, the total concordance of all electroencephalographic interpretations was 70 per cent for the one-egg and 10 per cent for the two-egg twins.

[8] Gibbs, F. A.; Davis, H., and Lennox, W. G.: The Electroencephalogram in Epilepsy and in Conditions of Impaired Consciousness, Arch. Neurol. & Psychiat. 34: 1133 (Dec.) 1935.

[9] Gibbs, F. A.; Gibbs, E. L., and Lennox, W. G.: Electroencephalographic Classification of Epileptic Patients and Normal Control Subjects, Arch. Neurol. & Psychiat. 50: 111 (Aug.) 1943.

Details of the rhythmic dart-dome sequences that appear in the electroencephalographic record during a petit absence vary from patient to patient. In the recordings of identical twins, details of the dart-dome formation are much alike.

In figure 4 are compared short sections of the tracings of Constance and Kathryn McN., 11 year old girls who have had frequent daily petit absences for the past three years. In spite of the similarity of their tracings during a seizure, trimethadione [10] has been effective in controlling the seizures of only one of the girls.

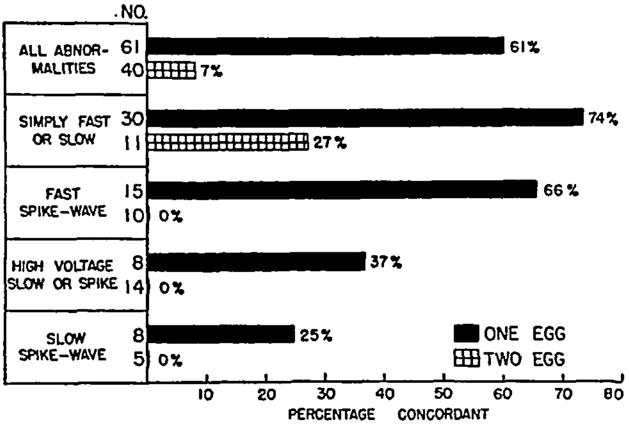

Fig. 3.—Concordance of electroencephalographic patterns in twin pairs. The solid bars represent one-egg, and the hatched bars, two-egg, twins. Percentages in which both co-twins have the same primary disturbance of the brain waves are at the end of the bars. Numbers at the base show the number of twin pairs in the group. The abscissa gives the percentage scale for concordant records. Only the outstanding abnormality is used in classification.

This striking likeness of brain wave abnormalities in persons with the same heredity adds weight to our earlier suggestion [7] that brain wave dysrhythmia might be the observable expression of the unseen, but long-talked of, anlage, or predisposition to seizures. However, the greatest concordance in identical twins and in the parents of epileptic patients is a mere alteration of background frequency. This clue becomes lost in the crowd of mere fast or slow waves of normal voltage in the general population—a 10 to 20 per cent incidence.

The following case illustrates the thinness of the line between symptomatic and asymptomatic cerebral dysrhythmia. Alice and Arlene D. are 10 years of age and are classed as one-egg twins without brain damage. During pregnancy the mother had eclampsia and experienced one convulsion just after the induced delivery of the twins. She also has a history of migraine. Alice, at the age of 3 years, received a blow on the head which rendered her unconscious for half an hour. At the age of 8, she began to have brief periods of unconsciousness. Later she had two mild convulsions. On two occasions, Alice's electroencephalographic record contained frequent discharges consisting of one or two spike-wave formations, occurring for the most part in the occipital and parietal leads but occasionally extending through all leads. She also had continuous 3 per second spike-wave discharges, persisting for approximately 10 seconds, during a petit absence. Seizures had never been observed in Arlene; yet her electroencephalogram contained rather more spike-wave discharges than did the record of Alice. On two occasions, when performing hypernea, she had a continuous spike-wave discharge lasting five seconds, accompanied with rhythmic blinking of the eyelids and failure to respond. Illustrative samples of the resting records appear in figure 5. Therefore, Arlene is electrically as epileptic as Alice. The division between symptomatic and asymptomatic dysrhythmia in this person was very thin, and was blown away by a few deep breaths. In Alice there was some externalizing agent which made her epileptic, possibly the blow on the head at the age of 3 years. However, the frequency of spike-wave discharges in Arlene, with the multiplicity of spikes, makes it

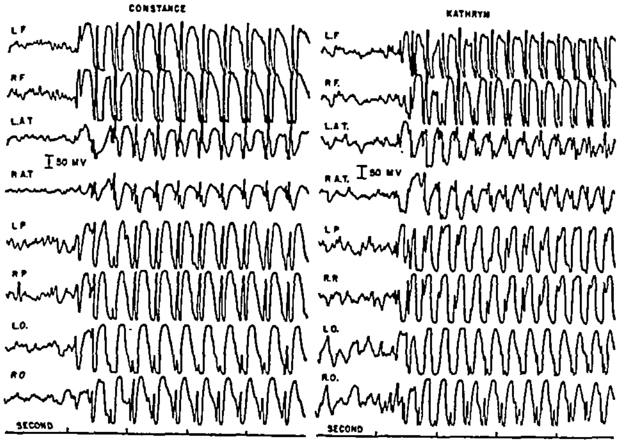

Fig. 4.—Samples of the electroencephalographic tracings of identical twins, Constance and Kathryn McN., aged 11 at the onset of a petit absence. There was no family or personal history of epilepsy. The letters at the left of the tracings indicate placement of electrodes, namely, left and right frontal, left and right anterior temporal, left and right parietal and left and right occipital leads. The signal in the middle indicates the deflection made by 50 microvolts. Time, in seconds, appears at the bottom. Reference leads were on the ears. The samples illustrate the likeness of the seizure pattern, even in some of the finer details, such as the tendency of spikes in the anterior temporal leads to surmount the waves and the relatively short spikes in the occipital leads. In the parietal leads, however, the placement of spikes is different.

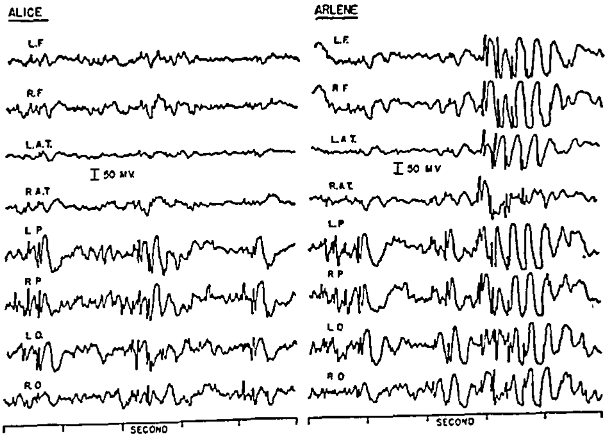

Fig. 5.—Samples of the tracings of Alice and Arlene D., one-egg 10 year old twin girls, taken in a period when free of clinically detectable petit absence. The symbols are the same as in figure 4. Alice (left hand panel) had had psychomotor equivalents daily for the past 18 months. Arlene (right hand panel) had had none except once, when performing overventilation.

---

10. Lennox, W. G.: The Petit Mal Epilepsies and Their Treatment with Tridione, J. A. M. A. **129:** 1069-1073 (Dec. 15) 1945.

probable that she likewise will have both petit mal and grand mal. In addition, the chance of epileptic offspring is equally great for the two girls.

In spite of the evidence that abnormal, as well as normal, patterns of electrical activity are transmitted, as shown by evidence of one-egg twins, parents of epileptic children with dysrhythmia may not show abnormalities of their electroencephalogram, or these may be of a minor nature—merely some slowness or fastness of the dominant rhythm.[1] This may be due in part to the fact that brain activity is a fluid trait and abnormalities of rhythm tend to disappear as the person grows older. This is especially true of the rhythm most characteristic of epilepsy, namely, the fast spike-wave formation. The slow form, resting on a pathologic basis, is more resistive to the healing influences of age and medicine.

HEREDITY OF MENTALITY

To the epileptic, maintenance of normal mentality is as important as control of seizures. Therefore, this matter deserves brief consideration. Twin studies have shown that the difference in the intelligence quotients of one-egg co-twins is small, much smaller than the spread between two-egg co-twins. In our own series of nonepileptic twins,[11] the average spread for 47 identical twins was 6 points and for 16 nonidentical twins, 10 points. Psychometric tests were given to 87 of the twin pairs of this study. The average spread in groups of twins was as follows:

Considering the twins without gross damage first, for the 17 one-egg twin pairs, both of whom had chronic epilepsy, the average spread was 7 points. In another group of 17 one-egg twin pairs in whom the epilepsy was chronic in one co-twin and only transient in the other, the average intelligence quotient for the severely affected twin and that for the lightly affected twin were exactly the same, 99. For 28 two-egg twins one of whom had chronic and the other transient epilepsy, the average intelligence quotient for the severely affected co-twins was 7 points lower than that for the lightly affected ones.

In contrast are those twins in whom one co-twin had at some time suffered gross damage of the brain with resulting chronic epilepsy and the other co-twin had no brain damage and only transient, or possibly no, seizures. For the 18 one-egg twin pairs, the average intelligence quotient of the brain injured with chronic epilepsy was 77, as against 104 for his relatively unaffected co-twin, a spread of 27 points. In the corresponding group of two-egg twins, numbering only seven, the average intelligence quotient of the chronic epileptic was 62, and that of his more fortunate co-twin was 93, a spread of 30 points. We may conclude that with mentality, as with convulsions, both heredity and acquired brain damage play important roles. The natural mental endowment of the patient is most important, and any gross anatomical impairment of the brain, especially if it occurs early, is of great influence. However, contrary to common medical opinion, the epileptic seizures themselves play a distinctly secondary role. This observation provides the clinician with a substantial basis for optimism when he talks with a patient (or parents of a patient) whose natural endowment is good and whose brain is not grossly damaged. A good brain can "take" a severe beating from epilepsy.

CLINICAL APPLICATIONS

A genetic factor in epilepsy is no longer in question, but only its nature and extent. As to its nature, the data from twins support the thesis that the fundamental transport is not of epilepsy per se, but of a predisposition to epilepsy. This is oftentimes demonstrable as a cerebral dysrhythmia. Possession of a predisposition to an illness is genetically the same as having that illness. As to extent, there is no reason to pillory epilepsy as a disease in which a predisposition is unduly conspicuous. As Galen remarked, "Always this is to be remembered—that no cause can be efficient without an aptitude of the body." Statistical studies which would include the use of twins would doubtless demonstrate that a transmitted "weakness," or predisposition, is greater for many common medical conditions than for epilepsy. On the basis of family histories, the hereditary factor in epilepsy appears to be approximately the same as that in diabetes, one-half that in obesity and one-eighth that in migraine, but no state has as yet forbidden migrainous persons to marry. Unjustified discrimination in this case is born of fear. The success of present day therapy of seizures should reduce both fear and discrimination.

The matter of extent applies also to individuals. Our 20,000 relatives and 122 twins told us only their total average experience. However, the patient wants of his doctor an answer to his own individual perplexity. "Can *I* get married and have children?" The child of the nonexistent Mr. and Mrs. Average would have a 30:1 chance of remaining free from seizures, whereas the chances might be 10:1 for Mr. Riley or 100:1 for Mrs. Levi, both of them real persons. Conditions that alter the chances have been stated elsewhere.[12] Briefly, those that minimize the likelihood of a epileptic child are a family history devoid of epilepsy or migraine for the spouse, as well as for the patient, and minimal abnormality of their electroencephalograms; some acquired condition that is at least partially responsible for seizures; late onset of the illness, and a normal mental endowment. Other modifying conditions may emerge as the data at hand are subjected to further analysis.

CONDITIONS THAT FAVOR MARRIAGE

As suggested at the beginning, persons are "carriers" of not one, but a great many, qualities. These transmitted traits determine, or help to determine, not only physical structure and physiological function of the body, but also the even more important characteristics of intelligence, personality and social consciousness. A person's intellectual and social assets may outweigh his physical liabilities. Hence, the physician must view the prospective parents (when one is epileptic) and ask himself, "Are the transmissible traits of mind, heart and body of such quality that reproduction is justifiable or perhaps advisable?" Some prospective parents should be discouraged; some encouraged. Unfortunately, persons who should be encouraged are the ones most alive to their social responsibilities and most likely (unless advised otherwise) to forego parenthood.

[11] Lennox, W. G., and Collins, A. L.: Intelligence of Normal and Epileptic Twins, Am. J. Psychiat. **101**: 764, 1945.

[12] Footnotes 1 to 11. Lennox, W. G.: Science and Seizures, New York, Harper & Brothers, 1946.

CONCLUSIONS

A history of seizures was obtained for 3.2 per cent of the 20,000 near relatives of 4,231 epileptic patients. The incidence was 3.6 per cent if evidence of brain damage prior to the patient's first seizure was lacking, and 1.8 per cent if such evidence was present. These percentages are, respectively, seven and 3.5 times the incidence of epilepsy among draftees for the United States Army.

As additional evidence of a genetic factor, in the group with undamaged brain (essential epilepsy) the incidence of epilepsy among relatives decreased progressively with a later onset of seizures (7.6 per cent if onset was in infancy; 1.5 per cent if it was after the age of 30). Corresponding incidences for the group with brain damage (symptomatic epilepsy) were 2.9 and 1.3 per cent.

The relative influences of heredity, brain damage and chronicity of seizures were studied in a group of 122 twin pairs affected with seizures. In twin pairs without prior brain damage, both co-twins were epileptic in 84 per cent of the one-egg and in 10 per cent of the two-egg twins. In pairs with brain damage, the corresponding incidences were 17 and 8 per cent.

In one-egg twins, concordance was usual not only with respect to seizures, but also with respect to the type of seizure and to the electroencephalographic pattern.

Intelligence quotients were determined for 87 twin pairs. The person's mental endowment was of most importance in the maintenance of a good intelligence. Acquired brain damage was a severe depressant; the reputed bad effect of repeated seizures was not in evidence.

A transmitted predisposition to seizures and brain damage are each (or both) important factors in the origin of a person's epilepsy. A constitutional cerebral dysrhythmia may, among other things, be the visual representation of a predisposition to seizures.

The genetic factor in epilepsy is probably no greater than in it is many other common diseases. The epileptic is unfairly pillorized in public opinion and in law. Assets that are transmissible, such as sound vital organs, good intelligence, personality and social responsibility, may outweigh the liability of a tendency to seizures. Hence, advice regarding marriage and children must be individualized.

ABSTRACT OF DISCUSSION

Dr. Knox H. Finley, San Francisco: This paper leaves little room for argument, for Dr. Lennox has remained conscientious to the facts uncovered by his many years of study on this problem. Throughout the paper, we recognize a constant and unprejudiced awareness of the epileptic problem from all angles. He has established that in the great majority of epileptic patients one is not dealing with the dichotomy of heredity versus environment. In the words of Dr. Stanley Cobb, in his monograph on the "Foundations of Neuropsychiatry," "The idea of 'versus' is wrong. Inborn behavior (healthy or otherwise) is there to start with; its substratum is carried by the genes, but the forces of maturation and the environment work with it to develop normal (or abnormal) behavior." Dr. Lennox' observations and conclusions not only are illuminating to the neurologist but open the door to the psychiatrist to broaden his perspective in not taking for granted or forgetting the forces of the genes or heredity, in addition to the equally important environmental influences, both physical and situational. The term "psychomotor," a term about which many of us are not happy, recognizes, nevertheless, the close relation of psychiatry to the epileptic problem. This is a further score against the dichotomy of medical neurology and psychiatry. In his comment on the concordance of types of seizures in one-egg twins, he gives the percentages of grand mal and petit mal seizures in co-twins as 70 per cent, psychomotor seizures in one co-twin occurring in only 17 per cent of one-egg twins. I should appreciate any comments he would have as to the significance of this.

Dr. Robert B. Aird, San Francisco: One aspect of this subject deserves some emphasis. When we speak of epilepsy as being inheritable, I believe we should define exactly what we mean. The high incidence of epilepsy and similar brain wave patterns in one-egg twins, found by Dr. Lennox, strongly suggests that the type of cerebral tissue and its pattern of functioning (that is, its physiology and biochemistry) are inheritable characteristics. This means that if one of a pair of one-egg twins has shown a susceptibility to convulsions, there is an excellent likelihood that the other possesses a similar tendency. Without intention of contradicting Dr. Lennox' findings, I believe we should stress that it is the type of tissue and its unstable pattern of functioning that is inheritable. One inherits, not spells themselves, but, rather, a susceptibility to them, as determined by the lack of physiological and biochemical homeostasis of the inherited cerebral tissue. The importance of this distinction lies in our attitude toward convulsive disorders and our approach to their therapy. We should not draw the conclusion, from Dr. Lennox' report, that epilepsy is inheritable, and let it go at that. When Dr. Lennox states that an abnormal electrical activity of the brain underlies epilepsy, or that epilepsy is a paroxysmal cerebral dysrhythmia, one might be so tempted. The point I am trying to make is that epilepsy is, fundamentally, a physiological and biochemical phenomenon and that the associated brain wave patterns and clinical spells are merely manifestations of the underlying abnormality. There is a tendency, in speaking of epilepsy as inheritable, to think of the physiology and biochemistry of the brain as fixed, and to forget such mechanisms as the patient's water and acid-base balances in the practical therapy of convulsive disorders. Given a susceptible background, convulsions may be induced by many acquired and variable factors, such as cerebral damage and certain shifts of physiologic and biochemical factors. Since such factors explain why patients have spells at one time and not another, and since they can be controlled in some measure, it is of considerable importance that we set about to regulate them. Let us not say, therefore, that epilepsy is inheritable but, rather, emphasize that the type of cerebral tissue, with its instability of functioning, is the characteristic which is inherited.

Dr. William G. Lennox, Boston: Dr. Finley's question about psychomotor seizures is, I believe, readily answered. Not only psychomotor seizures, but the slow spike-wave formation, which is found so often in children, carries a low concordance incidence; i.e., occurrence in both co-twins is relatively infrequent. This may be explained by the fact that both psychomotor seizures and the slow spike-wave electroencephalogram are usually based on some antecedent brain damage. A related question is this: If a hereditary factor is important, why do only 84 per cent of identical co-twins without evidence of brain damage have epilepsy? Probably there are many acquired abnormalities of the brain which one cannot recognize clinically. The brain pathology in this series refers only to gross damage, extensive enough to be demonstrable by the clinical history of brain damage or of focal seizures or by the pneumoencephalogram or the electroencephalogram.

In answer to Dr. Aird: Ordinarily there is agreement between the neurological evidence of localized brain injury and the electroencephalographic pattern. I am sure, however, that we do not have as close an agreement as Dr. Aird, because we have not been as meticulous as he is in carrying out localization studies. I agree with Dr. Aird that it is important to search for acquired factors and that even the brain wave pattern is not the final answer to the origin of seizures. The hereditary characteristic is represented by a gene, which is probably a large protein molecule; so if we are to pursue this elusive problem of the origin of epilepsy into its ultimate lair, we must go even beyond the neurophysiological mechanism of brain cells and demonstrate these protein molecules, and for complete eradication of genetic epilepsy, we must beneficially modify their configuration.

DIAGNOSTIC DRIFTS, DECEPTIONS AND COMMON MISSES

M. Pinson Neal, M.D., Columbia, Mo.

When a patient presents himself to one of you as his physician, a mystery is faced. You accept this fact and attempt to unravel the mystery. No one can boast the ability to set out alone, make correct diagnoses and fathom the nature of all diseases, any more than one can chart the course of a given disease or make of an individual case an average case.

Effective treatment is the aim of all medical practice. Early and accurate diagnosis is imperative if treatment is to be effective. It is the general practitioner to whom the average patient first appeals for help; therefore, the former bears singular responsibility. Many diseases are self-limited; some that otherwise carry a high mortality rate are curable when promptly recognized and adequately treated. To treat diseases without a diagnosis and without a knowledge of their behavior may be no more effective than trying to warm one's feet by moonlight.

Sometimes it is as important to know what kind of patient has the disease as to know what kind of disease has the patient. For the general practitioner of the early part of this century there were 24 hours in each day—he had time, or at least took time, to listen to the patient's and the family story. He usually knew of the feuds and fights in advance and took that information into account. He was not concerned with noonday luncheon clubs, golf courses, automobile races, fishing rodeos, the many present day medical and hospital staff meetings to be attended, and Wednesday and Saturday afternoons and Sundays off, and he was not pestered with fund drives for every imaginable thing except a retirement fund for broken down men of medicine. To him duty implied service—and serve he did! He brought to the sickroom an air of cheerfulness, confidence and optimism, though his treatment was sometimes founded on tragic errors of diagnosis. Too often today, however, physicians on the first visit start many patients on one of the antibiotic or so-called miracle drugs without seriously attempting a diagnosis.

The indiscriminate use of the "wonder" or "miracle" drugs without first determining the nature and cause of the disease is making a lost art of diagnosis. Changes in clinical picture and modification of signs mask or conceal symptoms and in some instances are the cause for depriving the patient of needed specific therapeutic agents. Truly, diagnosis should be a prerequisite for treatment, and patients, not their microbes, should be considered and treated. In the treatment of many infectious diseases there are bacteriostatic, virostatic or rickettsiastatic agents that may retard or repress the growth of infectious agents, but the body must still develop and exert its own defenses as antitoxic, immune body and cellular reactions. In many diseases immunity needs to be developed or borrowed immune products employed.

The treatment of the damages caused by microparasites, is a special task that requires medical ingenuity, experience, skill and individual attention. The physician is still faced with this problem even though the "miracle" drugs may have made possible the control of pathogenic micro-organisms. In chronic brucellosis this is very evident. In diphtheria, botulism and tetanus, antitoxic substances are still necessary to combat the soluble products having toxic action. Most diseases are relatively simple to restrain and cure in their early stages but become increasingly difficult to manage with each day of neglect or improper treatment. Too often a physician is called or starts diagnostic investigation after what began as a small snowball has rolled downhill to become an avalanche.

Is there too much diagnostic emphasis placed on information obtained from the many laboratory tests? There can be no substitute for a carefully taken and weighed history, with examination and observation of the patient by competent clinicians. Without this information, intelligent use of the laboratory as a diagnostic aid is not possible. Tests, no matter how well done, will not do the thinking for the clinician. Laboratory tests and roentgenologic observations are important in confirming and, in many instances, in establishing diagnosis; however, they are not always employed with judgment. Such a diagnostic approach, neglecting or misinterpreting history and physical findings, reveals lack of understanding by the physician and may be conducive to mischief, loss of valuable time and unnecessary cost. Be you reminded, however, that "he who practices medicine without the aid of a laboratory belongs to a past generation of physicians."

The subject under discussion is one with which I am familiar through years of experience as a consultant and active pathologist. In considering the deceptions and common misses as problems in diagnosis, I have given thought to means whereby those of the past could have been prevented and repetition in future cases avoided.[1]

PYREXIA

Body temperatures are commonly elevated as a more or less physiological process. Such elevations occur in metabolic diseases, such as acidosis and eclampsia, in conditions involving tissue necrosis, such as infarctions and the disintegration of blood clots, and in the infectious diseases in general. It is not uncommon for patients in the terminal stage of a fatal illness or for those severely ill with an infectious disease, especially the aged with pneumonia, to have normal or subnormal temperatures as evidence of little or no resistance. Certainly, it is true that failure for fever to develop in response to a severe infection calls for a grave prognosis. Unexplained fever is a frequent cause for extensive studies and anxiety on the part of the physician and patient. Among conditions where this is an occurrence are malignant diseases, especially Hodgkin's disease with its rather characteristic Pel-Ebstein, or Murchison-Sanderson, type of fever, toxic goiter, tuberculosis, syphilis, undulant fever, thrombosis-embolism-infarction phenomena and nervous exhaustion.

Professor of Pathology, University of Missouri, School of Medicine.

Read before the Joint Meeting of the Section on General Practice and the Section on Pediatrics, at the Ninety-Ninth Annual Session of the American Medical Association, San Francisco, June 30, 1950.

[1] Neal, M. P.: Diagnoses Commonly Missed in General Practice, South. M. J. 40: 414-420, 1947.

MALIGNANT DISEASES

Malignant neoplastic diseases, including the leukemias and Hodgkin's disease, frequently give rise to obscure and prolonged fever. Numbers of autopsies have been performed upon victims of undiagnosed malignant diseases who had a history of prolonged fever of undetermined origin. The accompanying manifestations of anemia, loss of appetite, loss in body weight, fatigue, insomnia, the localizing hemorrhage from some tissue or body cavity, the painless jaundice, the retention of secretions or excretions, the evidence of local obstructions, such as difficulty in swallowing, and constipation, call for investigation and explanation. Biopsy of an available lesion or of a regional or sentinel lymph node and roentgenologic examination, particularly with use of opaque substances for the demonstration of abnormal openings and communications, displacements, stenoses, filling defects and other abnormal features, should make for ready diagnosis of the solid tumors. The diagnostic blood findings or, when in the aleukemia phase, bone marrow films, make the diagnosis of leukemia easy.

UNDULANT FEVER (BRUCELLOSIS)

Brucellosis, an important disease of a specific bacteriological type, is accompanied with many complaints of chronic or recurrent nature. Masquerading under many forms and symptoms, it can be diagnosed without reasonable doubt only on isolation by culture of the causative organism from the patient in the acute stage of the disease. A relative or presumptive diagnosis is commonly and properly made on a combination of repeated blood agglutination reactions showing a rising titer, and skin and opsonocytophagic tests. The diagnosis of Brucella infection or undulant fever on the basis of only one of these or, even worse, on the "therapeutic test" is not reliable. A skin test does not distinguish past infection from present active infection. The complacency of those who rely upon it is deprecated, for, all too often, it is misleading. If it shows a rising titer, the agglutination test is good presumptive evidence in acute cases, but some strains of the organisms are not agglutinated even by the serum of the patient from whom the strain was isolated. The agglutination test is positive more frequently in acute than in chronic cases of brucellosis, but complete agreement is absent concerning the agglutination titer level at which significance, or positivity, begins and from below which one would interpret a negative reaction. A "positive agglutination" may follow one or more skin tests from which the antigen has sensitized the individual. The recognition of chronic brucellosis is as difficult as would be the diagnosis of syphilis without the Wassermann or other serologic tests. Many patients whose condition has been diagnosed as chronic brucellosis have eventually been found to be free of that disease and to have or show evidence of having been suffering from a malignant growth, leukemia, Hodgkin's disease, toxic goiter, hypothyroidism, tuberculosis, syphilis or nervous exhaustion.

DISEASES OF THE THYROID

Hypothyroidism.—This condition, commonly encountered in obese, myxedematous and cretin types of persons as a major manifestation, is easily recognized, but when encountered in lower degrees, it is commonly missed. To this larger group belongs the hypothyroid person with sensitivity to cold, prematurely wrinkled dry skin, constipation, nervousness, vertigo, often a puffy face, and, generally, with a mental lassitude, particularly seen in the schoolrooms in "flunkers" or "repeaters." The subnormal basal metabolic rate, the most significant criterion in diagnosing the condition, evidences the metabolic disturbance that is responsible for most of the subjective findings. The administration of a potent thyroid preparation is most striking in its reward, bringing about the change of a follower to a leader, a dullard to a scholar, and a person of the vegetative type—indolent, indifferent, inactive, languorous, mentally and physically sluggish—into an active, ambitious, alert, energetic person possessing mischievous potentialities.

Toxic Goiter.—A toxic goiter can and should be recognized in a patient from the general symptoms, signs and history, the diagnosis being confirmed by the basal metabolism test. The patient, however, may have a history of low grade fever persisting for months and of going from one doctor or clinic to another. It is to be emphasized that a basal metabolic rate above normal may be the result of conditions other than hyperthyroidism and is a measure only of a metabolic disturbance and not of the mischief a goiter is doing.

SYPHILIS

Frequently syphilis, this "great imitator," a universal disease of man, in spite of all efforts at its control still escapes the dragnet of diagnostic procedures. One of the sundry manifestations is prolonged fever. Positive or negative serologic tests are not conclusive for or against the diagnosis of this disease. Symptoms, signs and history must be given full consideration. When there is reason for question after considering all these factors, spinal fluid examination should be made, including cell count, globulin determination, colloidal gold test and a serologic test, preferably the Wassermann.

Inadequate attention has been given the patient in whom the only indication of syphilis is a positive serologic test. The diagnosis of syphilis is particularly important in those states having a premarital blood test law to the exclusion of other methods of recognizing syphilis. The serologic tests miss the patient with syphilis in its most infectious period, the chancre stage, and yield positive findings to the highest degree in the later stage of the disease, when the patient is really harmful only to himself.

A number of conditions are now recognized as yielding false positive serologic reactions for syphilis: those caused by respiratory, infectious and febrile diseases, especially malaria and infectious mononucleosis, and those following immunization, significantly against tetanus and smallpox. In these conditions a clinical history, properly interpreted, a spinal fluid examination and repeated serologic tests will bring clarification. The repeated tests of serums will on quantitative determinations show a titer remaining at a constant level or possibly increasing in syphilis; whereas, in those serums giving the "biologic false positive reactions" the titer usually decreases or, in a majority of cases, gives a frank negative reaction within three months after subsidence of the responsible factor. In patients with these false positive reactions there are no false spinal fluid reactions.

VASCULAR ACCIDENTS

Thrombosis and Embolism.—The protective mechanism of blood coagulation as a physiological process may be harmful or even fatal, as in thrombosis, embolism and infarction phenomena. To the physician these phenomena remain the one great hazard to surgery as tragic complications to trauma, pelvic inflammations, vascular damage and pregnancy in the postpartum period. To the public they constitute one of the "acts of God" in the form of a visitation by the "Grim Reaper," taking the life of a patient who is in convalescence from one of the named conditions. Sudden death may occur dramatically in the patient in whom a fracture is progressing properly, in the postpartum patient when all is well and in the postsurgical patient who is ready for dismissal. Unexplained fever, anxiety and restlessness of the patient many times give warning prior to the development of dyspnea, cyanosis and shock as evidence of pulmonary embolism. Dislodgement of thrombi formed in some portion of the venous system and carried as an embolus or emboli to the right side of the heart and from there to the pulmonary arteries most often follows gastric and pelvic operations. Fatality usually occurs between the sixth and eleventh days following trauma, surgery or delivery. Life terminates as suddenly as the automobile motor stops from a gas line "vapor lock." Almost all of those who succumb to this condition do so within less than one hour of the first manifestation, and fully one half of them die within less than five minutes. Medical literature reveals that pulmonary embolism is responsible for 80 of every 1,000 postoperative deaths, for two deaths in every 1,000 operations and for one death in every 1,000 patients receiving hospital care.

The pulmonary symptoms of embolism are often unfortunately the earliest recognized manifestation of an unsuspected thrombus somewhere in the venous system. Thrombi are most likely to occur where there is venous stagnation, as in patients who because of the nature of their illness must be kept immobile, are obese and have known cardiac deficiencies and "poor circulation."

Myocardial (Cardiac) Infarctions.—Cardiac infarction has changed from a rather rare to a common disease. During the 10 year period ending in 1949, the number of cases of coronary thrombosis treated in the University of Missouri Hospitals was exactly twice the number that had been seen in the previous 10 year period. Prior to and during the first year of World War II from 20 to 25 patients a year were admitted to one Swedish hospital with coronary thrombosis with infarction of the heart. In 1948 there were 136 such cases, and the 25 among them ending fatally were verified by postmortem findings.[2] The high price paid for overwork, anxiety, worry and the great use of tobacco, as seen particularly in the medical profession with its death rate from coronary disease, is alarming. Not all patients exhibit the severe and classical diagnostic manifestations. Some of them escape diagnosis and suffer cardiac rupture or severe dilatation under exertion or during excitement. The patient unknowingly abuses his heart and shortens life because the primary lesion was unrecognized and he was not warned. Too frequently coronary arterial disease is diagnosed at the autopsy table.

Patients suffering this catastrophe need early diagnosis, for treatment centers predominantly on protection from further damage. The electrocardiogram in most cases shows changes which are diagnostic. The test should be repeated in the patient when it at first fails to show myocardial damage. A negative electrocardiogram in no sense indicates an undamaged myocardium. It is a valuable additional and supportive finding—not a final test. When there is absorption from an established area of myocardial necrosis, the blood sedimentation rate becomes more rapid than normal and so persists, even after the fever, the leucocytosis and neutrophilia have disappeared. This test is of significant value in differentiating myocardial infarctions from angina pectoris, in which it is unaltered.

ANEMIA

It has become a modern fad to have anemia, and for some physicians to make such a diagnosis and prescribe iron, transfusions, folic acid, vitamin B_{12}, liver or liver and gastric extract preparations, without the benefit of blood studies and other examinations that may be required to classify the anemia, if, indeed, it is present, and to determine such therapeutic need. The general practice of administering the specific anti-pernicious-anemia elements to patients in whom the condition has not been diagnosed as well as to those with the common anemias of iron or other deficiency, such as that following blood loss or produced by parasitic or bacterial infections, toxic, drug or chemical action, is illogical, wasteful of scarce agents, expensive and useless. The majority of patients suffering from anemia require iron replacement therapy, and, if the anemia is severe, transfusions of blood. In others the condition is soon corrected if the factor or factors of causation are removed.

NUTRITIONAL DEFICIENCIES

The nutritional deficiencies are many and vary as to cause, type, degree, tissues involved, manifestations, lesions and in requirement for therapy. One should ever be conscious of the fact that nutrition is to some degree involved in most diseases. A high percentage of the cases seen and treated in adulthood are the result of chronic alcoholism, for alcohol does not contain the vital food elements that it replaces. Nutritional disturbances may be the cause of anemia, delayed healing of surgical or traumatic wounds, prolonged convalescence, sterility, miscarriage, rickets, faulty bone and tooth development, osteomalacia, edema, neurological manifestations, digestive disturbances, and other conditions. The cause as well as the nature of these conditions must of necessity be determined before initiating treatment and applying corrective measures to prevent repetition.

Malnutrition can exist on "three square meals daily." Much of the thought expended on sex education, anti-alcohol and cancer control campaigns could with profit be expended on this problem. The cancer control program, laudable as it is, affects largely those of 50 or more years. Programs to make healthier men and women from the school children who still have 50 or more years of life expectancy should also have much attention and support. Experts estimate that millions of Americans are living—or worse, many are dying—on inadequate diets. Too many, particularly those of school age, reach for a candy bar, when they need a vitamin rich, wholesome apple or orange. In health-building programs there has been neglect in utilizing teachers who live in almost daily contact with millions of school children. Through these, education in health matters can be carried to their charges, and demonstrations are possible by frequent measurements and progress records for those having mental curiosity or interest. Nervous instability is becoming our national disease. Poor diet may be one of the chief causes of this condition.

---

[2] Malmros, H., cited in Infarction of the Heart, Foreign Letters, J. A. M. A. 142:275 (Jan. 28) 1950.

The child with a digestive disorder or an acute nutritional upset manifested by acidosis, nausea, vomiting, fever and abdominal pain may be given a diagnosis of appendicitis and be operated on, with resulting chagrin to consultant and surgeon who ignored the acetone-loaded urine, or failed to have a urinalysis done. In those cases the leucocyte count, which fails to show an elevated or rising neutrophil percentage, rules out infection.

Among industrial workers and outdoor men subject to heavy sweating and loss of sodium chloride, deficiency of this chemical may cause a serious metabolic disturbance bringing on myalgia or heat cramps, particularly of abdominal muscles, and may be mistaken for "an acute abdomen." A history usually suffices for diagnosis; if not, a simple chemical determination will reveal the deficiency which can be easily corrected.

INTERNAL PARASITES

Stoll[3] has estimated 44,900,000 human helminthic infestations in our population of about 144,000,000, or a population infection of 31 per cent. He terms trichinosis, oxyuriasis and uncinariasis as of special importance in this country. In routine examinations, urinalyses reveal diabetes mellitus in about 0.4 per cent, serologic tests for the diagnosis of syphilis yield about 2 per cent positive reactions and blood counts show a blood dyscrasia in a small fraction of 1 per cent. Internal parasites are ignored many times and commonly missed. In some locations physicians are ever conscious of the possibility of malaria, hookworm, Ascaris, Oxyurias and amebic infections. It would be most interesting to know what your individual answers would be to the question, "How many examinations for internal parasites or their ova were requested by me last year?" Trichinosis is to be considered especially in the patient who has typhoid-like symptoms, with a negative blood culture and a negative Widal reaction. Malaria is often missed because the patient had been taking an antimalarial drug in amounts sufficient to reduce the numbers of parasites in the circulating blood, making their finding difficult or impossible. Amebiasis is usually missed by the employment of an unsatisfactory technique.

NERVOUS EXHAUSTION

Emotional and neurotic disturbances, psychoneuroses, functional nervous disorders, neurasthenia and constitutional inadequancy are acceptable as expressions of a condition, if not as diagnostic terms. These constitute not pathological entities but psychological elements, which the general practitioner finds are as hard to interpret and, often, just as important as are the physiological and anatomical factors. Within the last three decades nervous exhaustion has become a fairly common condition, yet many times it is missed, or the symptom complex is misinterpreted. An ever increasing number of individuals who are physically and possibly mentally exhausted and living in anxiety states have prolonged, unexplained fever and other symptoms without demonstrable organic basis. For some, our modern way of living is just too unsettled and strenuous. In these patients, rest, relaxation, relief from responsibilities and anxieties, change of environment and a regulated schedule of work and play with a balanced diet work magic. It frequently becomes necessary that such a patient be told, "Your symptoms are real enough, but they are not being produced in an organ that a surgeon can remove and they are not amenable to any drug or chemical agent." The Chinese writer Lin Yutang has been credited with saying, "American worship of hard work is a national cross on which men crucify themselves," and yet the great English philosopher and bishop Richard Cumberland proclaimed, "It is better to wear out than to rust out."

SUMMARY

A plea for definite and early diagnosis as a prerequisite for prompt and applicable therapy is made.

ABSTRACT OF DISCUSSION

Dr. Oscar B. Hunter, Washington, D. C.: To the pathologist it is sometimes disconcerting to find that physical examination, careful history of case and mental concept vary from the clinical examination, which has not been made by the clinician. He must allow the intern or resident or someone else to do it, or the laboratory tests are taken at their entire face value. I have always told my students, "No matter whether your test comes out this way or that, if you disagree with your clinical findings, take the clinical findings and check your laboratory test." It is also distressing to see tests of all kinds on the patient ordered without reference to the clinical manifestations. That is not good practice. We would much prefer to work directly under the physician or the pediatrician, and prove or disprove a patient to be suffering from the condition which he suspects. I would like to hear Dr. Neal say a word about the newer tests for malignant conditions, particularly from the serologic standpoint. Many such tests have proved unsatisfactory. Syphilis is always with us and offers a difficult problem of diagnosis. At least 42 other conditions may be confused with syphilis. Treatment should not be based only on a positive Wassermann test, but on the clinical manifestations plus any assistance that can be given by the Wassermann test. It is unfortunate that an individual is labeled syphilitic when he has no syphilitic manifestations other than a positive serologic reaction. I think we have a much better understanding, particularly in the postoperative cases, of the development of phlebothrombosis or thrombophlebitis in the leg, with the attendant difficulties in the lungs with formation of massive or minute emboli or infarcts. Lead poisoning could be discussed at length. A machinist working in a Navy yard was dismantling an old ship and burning off paint with a blow torch. Pain developed, and he was about to be operated on for appendicitis, when the blood count showed he had a large amount of basophils in his blood. The diagnosis of lead poisoning was made and the man's life saved. Dr. Neal has called attention to many important matters that need to be reviewed, and we trust that our misses will become fewer.

Dr. J. B. Bilderback, Portland, Oregon: At times, it is difficult to determine the cause of fever in a child. Frequently one will do the most careful physical examination and have the support of a good laboratory, and nevertheless be unable to determine what is causing the fever. It often takes all one's training and patience to make the right early diagnosis of acute abdominal pain in young children, particularly in beginning appendicitis or intussusception. Examination of a child with unexplained fever is not complete unless one or several examinations of urine are made. Malformations of the urinary tract are rather common in children, as autopsies reveal an occurrence of 5 to 12 per cent malformation. The crux of Dr. Neal's paper is that one should make the diagnosis early and be sure what is wrong before treatment is started. Ideally, that is true, but it is sometimes very difficult, particularly in cases where you might have beginning meningitis and do not know the type. In meningitis, especially, every hour counts, because your results depend largely on how soon treatment is started. We have witnessed one of the most wonderful decades in therapeutics. The sulfonamides and the antibiotics have followed each other so closely that we are hardly used to one before we have another. And now we have the antihistamines, ACTH (pituitary adrenocorticotropic hormone), cortisone and their new cousins. Let us all hope now that the test of time will prove their worth.

---

[3] Stoll, N. R., in Karsner, H. T.; Lund, H. Z., and Sanford, A. H.: The 1947 Year Book of Pathology and Clinical Pathology, Chicago, The Year Book Publishers, Inc., 1948, pp. 512-518.

Dr. M. Pinson Neal, Columbia, Mo.: As far as the newer procedures in the diagnosis for malignant growths are concerned, as a morphologic pathologist I believe in the biopsy, the histologic section properly interpreted being the one conclusive means of arriving at a true diagnosis. None of the chemical tests are accepted as diagnostic in a given case. Exfoliative cytological diagnosis has its place in a screening program, but it is not depended on by even its strongest adherents as a final criterion in an individual case, at least for radical surgery. Dr. Bilderback mentioned starting treatment without having an established diagnosis. The trouble with this is that most of the modern drugs and agents modify symptoms, and therefore one loses the guiding light that points the way and the crutch that helps carry one to certainty. The use of one of the "miracle" drugs as a therapeutic agent without an established diagnosis of the disease is a too common trend or drift. The acceptance of reports on some laboratory procedures as diagnostic, when false positive reactions are common and are not duly considered, constitutes deception. Failure to obtain an adequate clinical history and to employ definite diagnostic procedures may be responsible for numbers of diagnostic misses.

RINGWORM OF HANDS AND FEET

HISTORICAL REVIEW

James Herbert Mitchell, M.D., Chicago

In my paper entitled "Ringworm of Hands and Feet," which was read before the annual meeting of the American Medical Association in June, 1916, at Detroit, and which was published in The Journal, I stated as follows[1]:

> Tilbury Fox was probably the first observer to report a recognized case of trichophyton infection of a volar surface. The diagnosis in his case was simplified by the fact that the lesion began on the dorsal surface of the hand as a typical ringworm, and gradually progressed until it involved the interdigital and palmar surfaces of the fingers. In 1888, Pellizari reported the occurrence of seven cases of infection of the palms and soles in a series of 150 cases of trichophytosis capitis. The first careful and systematic study, however, was not made until 1892. In January of that year, Djelaleddin Moukhtar, working in Fournier's clinic, presented two cases before the Societe de dermatologie. They were of the eczematoid dyshidrotic type, with abundant mycelial threads, and excited much interest and discussion by the societe. During that year, four more papers by the same writer appeared. In the last of these he collected reports of twenty-five cases, seventeen of which were personal observations.
>
> In 1908, Whitfield described five cases of ringworm of the hands and feet "indistinguishable from an ordinary outbreak of acute vesicobullous eczema." In 1910, Sabouraud reported six cases of intertriginous eczema of the feet, four of which gave cultures of Epidermophyton inguinale, and one case with lesions on the hand. In February, 1911, Whitfield recorded observations in seven additional cases. In November, 1911, Sabouraud presented his observations on the subject at a special meeting of the Dermatological Section of the Royal Society of Medicine. The discussion was opened by Whitfield with a paper in which he classified the clinical types and reported fifteen additional cases. In the general discussion which followed, most of the members present told of having encountered the disorder among their private patients.
>
> Since 1911, the most comprehensive paper on the subject is that of Kaufmann-Wolff. She made a clinical, histologic and mycologic study of twenty-five cases which formerly would have been accepted as dyshidrosis. In America, Montgomery and Culver reported an infection of the feet, following eczema marginatum of the groin, from which Epidermophyton inguinale was grown. In 1915, Hartzell reported four cases which he had seen "in the past few years."
>
> In 1916, Lane reported two cases, both of which were in women. One patient had lesions on the plantar surface of the foot, and the other had lesions involving the nails and both dorsal and palmar surfaces of the fingers.

Prior to the publication of the papers by Hartzell and by Lane, the condition had gone practically unrecognized in the United States. After the publication of my paper in 1916, interest in the subject was aroused and there came a rapid acceleration in the number of papers appearing in the medical press until to date there is now a bibliography approaching 300 full length papers.

At the present time, papers on ringworm of the hands and feet are about as frequent as talks on "Low Back Pain," "The Acute Abdomen," and "Some Common Skin Diseases Seen in General Practice." I am unable to estimate the number of times my lantern slides of fungous diseases have been lent to speakers who were qualified to discuss the subject but who had failed to provide themselves with the necessary slides.

In the original paper in 1916, a careful study of 65 cases was reported, and photographs of the various manifestations of ringworm of the hands and feet were presented. A careful reading of that paper leads me to say that no statement made therein calls for retraction to date.

At the annual meeting of the American Dermatological Association in 1921, I read a paper entitled "Further Studies on Ringworm of the Hands and Feet."[2] The differential diagnosis, the methods of culture of the organisms, and the types of organisms found were set forth. In that paper, the whiskey flask was described as being very useful by way of providing large surfaces for giant cultures without the necessity of making subcultures.

Distinguished Lecture in Dermatology, read before the *Section on Dermatology* at the Ninety-Ninth Annual Session of the American Medical Association, San Francisco, June 29, 1950.

[2] Mitchell, J. H.: Further Studies on Ringworm of Hands and Feet, Arch. Dermat. & Syph. 5:174 (Feb.) 1922

At the annual meeting of the American Dermatological Association in 1922, I read a paper on "Erosio Interdigitalis Blastomycetica." This condition was first described by Gougerot and Goncea in 1915, and later by Fabry in 1917, but my case was apparently the first to be reported in this country. It was seen Aug. 10, 1921, and was presented at the January meeting of the Chicago Dermatological Society in 1922. The condition is due to Monilia (Candida) infection and is usually found in the third interspace of the fingers. The first cases seen were limited to obese, orthodox, Jewish women. Further studies showed that Monilia infections are essentially intertriginous.

In a paper entitled "Amycotic Dermatoses Simulating Ringworm and Erosio Interdigitalis Blastomycetica," read before the annual meeting of the American Dermatological Association in 1928, I stated[3]:

> My purpose in this paper is to call attention to a series of cases in which lesions were presented that simulated ringworm infection and erosio interdigitalis blastomycetica, but in which a fungus could not be found. Some of the lesions may not be acknowledged by experienced clinicians as even resembling ringworm, whereas other lesions of this group will probably call forth emphatic insistence that they are ringworm, and that I have failed to demonstrate the organism. My answer to such insistence is that I have no proof to offer other than negative mycotic results.

Quoting further, I said:

> Bacteria as the causative agents of dyshidrotic eruptions seem to have attracted little attention. Rajka, however, is convinced that staphylococci and streptococci may produce such eruptions, and he described in detail a group of six cases. In his series, the dyshidrosiform, symmetrical eruption was usually preceded by an impetiginous lesion. The vesicles, which were sterile at first, became infected in the course of from one to three days and contained pus cells. He was unable to determine the pathogenesis of the symmetrical outbreak. The condition might be allergic, he thought, or a hematogenous dissemination either of the organisms or of their toxins. Rajka concluded that there are three forms of dyshidrosis: mycotic, microbic and nonparasitic. He stated the belief, however, that further study might lead to the placing of many of the cases of the third group into one or the other of the first two groups.
>
> In general, the nonmycotic lesion in the group of cases that I am calling attention to does not resemble dyshidrosis. The lesion is more superficial than ringworm, and is not characterized by a deep-seated vesicle as is the mycotic infection. The lesion usually has a well-defined advancing border, but the individual element is a minute, yellow, serous plug rather than a deep-seated vesicle. There is less variation in the components of the lesion than in ringworm. The coexistence of pustular lesions elsewhere on the body is a fairly constant feature of all of this group of cases.

Continuation of studies on bacteria as a possible cause of lesions on the hands and feet simulating mycotic infections resulted in the presentation of a paper before the Section on Dermatology at the annual meeting in Cleveland in 1934. In the summary of this paper, I stated[4]:

> There is a marked tendency to regard all acrodermatoses as ringworm of the extremities.
>
> There is a need for careful laboratory examination of all dermatoses of the hands and feet before arriving at a diagnosis.
>
> I agree with Sabouraud, MacLeod, Walker and Roxburgh that impetigo (Tilbury Fox) is due to the streptococcus; this fact can be proved with ease.
>
> A group of five cases of streptococcic infections (impetigo) of the extremities simulated mycotic infection sufficiently to lead to errors in diagnosis.
>
> The infections were found to yield within one week to baths of corrosive mercuric chloride and weak ammoniated mercury ointment.

The importance of demonstration of the presence of a fungus by microscopical examination or the culture tube is emphasized by the fact that in Illinois, ringworm of the hands and feet is not compensable as an occupational dermatosis. I have had a number of private patients with occupational dermatitis who were denied compensation on the statement of dermatologists that these patients had ringworm. These statements were made by dermatologists after inspection only and with no attempt at examination with the microscope and the culture tube. In occupational dermatoses, one of the commonest mistakes is to assume that because of the presence of clinical evidence of ringworm of the toes, any dermatosis of the hands is, therefore, of mycotic origin.

In 1934, I presented a paper at the annual meeting of the American Dermatological Association on "Monilia Infections of the Hands and Feet," in which I called attention to the essential differences in the manifestations of Monilia infection of the hands and feet from those produced by the Trichophyton and Epidermophyton organisms.

Monilia infections of the hands and feet are essentially intertriginous and symmetrical with little or no vesication as seen in the well-recognized manifestations of hands and feet. Monilia onychia is almost always preceded by "bolster-like" paronychia, first described by MacLeod, whereas the ordinary ringworm infections of the nails are usually devoid of any indication of paronychia.[5]

As chairman of the Section on Dermatology in 1927, I read a paper entitled "Need for Research in the Treatment of Epidermophytoses." In that paper it was stated[6]:

> During the past decade widespread interest in the fungous infections has been stimulated by an ever increasing number of papers on the subject from all parts of the civilized world, and by an ever increasing number of clinical cases, both in public and in private practice. Very little attention, however, has been devoted to the purely therapeutic side of the question. It is a noteworthy fact that the first intensive laboratory attack on the problem was made in this country by Schamberg and Kolmer (*Arch. Dermat. & Syph.* 6:746 [Dec.] 1922), who determined the fungicidal and fungistatic properties of various drugs and chemicals. Another valuable contribution to the subject was made by Meyers and Thienes (*J.A.M.A.* 84:1985 [June 27] 1925), and from these studies came their formula for the alcoholic solution of cinnamon oil and thymol, which in my experience has been a very valuable preparation."

Since that time many valuable contributions, which were the result of long range planning and careful execution, have been made on various phases of mycology, such as those of Peck and his co-workers on the fungistatic and fungicidal action of sweat and the fatty acids. Also the intensive research of Peck and others in the field of the problems pertaining to the trichophytins must be mentioned. The work of Weidman, Hopkins, Lewis, and others is too well known to all for me to need recall it.

CLINICAL MANAGEMENT

Notwithstanding all this investigative work, no great stride has been made in the clinical management of the epidermal mycoses. Various new methods of treatment have been proposed but have been attended by disappointing results, prohibitive complications of technique, or dangerous sequalae.

In any discussion of the therapy of a cutaneous mycosis, there are certain factors that must be considered. One is the resistance, or if one prefers, the susceptibility of the person to a given fungus. It is a commonplace that patients will recall having had maceration in the fourth pedal interspace for 25 or 30 years without having had any other manifestation of ringworm. Being one of these persons, I have had ample opportunity to observe the mildness of the process.

Another factor which is most difficult to contend with is a sensitive skin. By this I do not mean necessarily a polyvalent sensitization, which is a real problem, but I refer to the skin that cannot tolerate two or three applications of half strength benzoic and salicylic acid ointment (Whitfield's ointment) without developing a luxuriant crop of follicular pustules of the Bockhart type, or two or three applications of chrysarobin, iodine, sulfur or mercury, without blossoming forth with an erythematous or vesicular dermatitis. In such instances, it is, according to my experience, necessary to stop all antiparasitic treatment and begin treatment of the dermatitis in the hope that it will subside.

The investigations of Peck[7] and his co-workers on the fungistatic and fungicidal effects of sweat and the fatty acids have resulted in tremendous advertising and selling campaigns for propionate-caprylate mixtures (sopronol propionate-caprylate compounds®) and zincundecate (desenex®) ointment. The essential ingredients in the former are caprylic and propionic acids and salts, and of the latter, undecylenic acid. Regardless of the opinion of others, it is my experience that both are of very little value in treatment of fungous infections.

The excellent work of Keeney[8] and his associates in the extensive and intensive study of the fungistatic and fungicidal activity of the fatty acids is convincing and impressive.

However, during the epidemic of ringworm of the scalp, I was searching for a fungicide that might be of value, and in so doing, I immersed hairs infected with Microsporum audouini in various preparations and planted them on solid medium. The organism grows as well or better with some of these preparations than without them.

My tests with Monilia (Candida) have been similar to that with hairs infected with audouini. Mixing equal parts of a thick creamy colony of Monilia with zincundecate ointment and planting on agar, I observed slightly smaller colonies at first, but eventually the growth was the same as that of the plant without the zincundecate ointment. Tests with propionate-caprylate mixtures ointment, benzalkonium chloride (zephiran chloride®), absorbine, Jr. (mixture of wormwood, thymol, menthol, iodine, echinacea, and calendula) and various other preparations gave similar negative results.

One episode in the treatment of dermatophytosis would have been very amusing if it had not resulted in such serious consequences. Paul DeKruif, who, after two years of undergraduate medical school training at the University of Michigan, has become the medical adviser to all the world via *The Reader's Digest,* pounced on an article by Dr. Francis, a retired United States Public Health officer. This short paper, in which the retired medical officer advised the use of camphor and phenol, appeared in THE JOURNAL of Dec. 6, 1941.[9] The good physician's enthusiasm was unbounded and uninformed. He advised the use of approximately equal parts of camphor and phenol and stated that it was nonirritating and very effective in the treatment of ringworm of the hands and feet. Obviously, neither Dr. Francis nor DeKruif knew anything of the background of this preparation.

In the early nineteenth century, one Italian physician and one French physician, independently, hit on the combination of camphor and phenol for sterilization of wounds and for application to various abscesses and infections in general. This combination was later to become a well-known preparation called campho-phenique® (mixture of camphor, phenol, and liquid petrolatum), marketed by a drug firm in St. Louis. The firm claimed that it contained 49% phenol and 51% camphor. The irritation and damage to the skin resulting from its use led to an investigation by the Council on Pharmacy and Chemistry, the report of which appeared in THE JOURNAL[10] and was signed by Dr. Puckner. Samples of the preparation, bought in the open market, showed that the formula had been changed so that it contained 20% phenol and 38% camphor; the rest was liquid petrolatum. This mixture is relatively innocuous compared with the combination of equal parts of camphor and phenol touted by Francis and DeKruif. The danger in the use of the equal-parts combination lies in the fact that in the absence of moisture it is inert and does not conduct electricity. However, addition of water to the mixture immediately releases phenol from the inert combination, as can be determined by the addition of ferric chloride. Phenol burns result, inasmuch as fungous infections are favored by the moist, interdigital surfaces of the toes. I was very busy for a year or more treating the results of therapy advised by a superannuated physician and espoused by one who had never graduated in medicine.

Ionic medication of the mycoses attracted much attention some years ago. In 1931, Shaffer[11] presented a comprehensive review of the literature and the value of the technique of the various dermatoses. Ten years later Greenwood and Rockwood,[12] limiting their investigation to the use of copper sulfate in the treatment of the mycotic infections, agreed with Shaffer that the method is "complicated, technical, tedious, and time consuming." They found that when copper sulfate was introduced into the skin by iontophoresis, it was neither fungicidal nor fungistatic for T. gypseum, T. purpurium, and Epidermophyton inguinale.

Inhalation of ethyl iodide has been found by J. H. Swartz [13] to be an effective method of treatment, but the words of Shaffer, quoted above, might be used again in the description of this treatment. An overdose may result in some embarrassment on the part of the physician.

Intravenous injections of various drugs, especially strong iodine solution (lugol's solution), have been extolled. Inspired by the enthusiasm of Levaditi, I gave a large number of intravenous injections of strong iodine solution some 25 years or more ago. The results consisted chiefly of an occasional sclerosed cubital vein.

In the management of the dermatomycoses, prophylaxis must be considered as important as treatment. Osborne has presented convincing figures showing the reduction of infections in schools by means of the chlorinated soda foot bath. Spring,[14] however, showed that scales were viable after soaking one and one-half hours in swimming pool water chlorinated to the point of tolerance, but that the organisms were no longer viable after soaking for two hours. It was found, moreover, that the chlorinated swimming pool water does not effectively reach and kill the fungi in the interspaces of the toes.

In an attempt by John W. Williams [15] to determine the habitat of Trichophyton interdigitale outside the body, 1,500 cultures were made, one-half of which were made from student lockers. Floors were scraped and the margins of pools were likewise scraped, but in all of the 1,500 cultures, only one possible positive culture was obtained and that could not be identified.

Jamieson and McCrea [16] were able to grow pathogenic organisms from the insoles of shoes, and the infection of a large number of girls in an orphanage after wearing cast-off shoes was clinical confirmation of his laboratory findings. Sterilization of shoes by means of formaldehyde has been routine practice by many dermatologists for years, and the wearing of boiled cotton hose is recommended by all. However, the indiscriminate use of formaldehyde is dangerous and may set up a chronic dermatitis.

TRICHOPHYTIN

The use of trichophytin in the diagnosis and treatment of the mycoses has been disappointing, but it appears that it is of more value in the diagnosis than in the treatment of the fungous infections. In a series of more than 1,000 tests, it was found by Lewis, MacKee and Hopper [17] that the reaction to trichophytin is specific, but the specificity is determined by genus rather than by species. Different species of fungi vary greatly in their ability to sensitize, and patients with severe mycoses may fail to react. However, in all cases of trychophytid reaction the trichophytin test gave positive results, as also in all cases of inflammatory eruption due to a given fungus. It was found that the patch test was not so delicate nor so reliable as the intracutaneous test. There was little difference in the response of the skin of different parts of the body. The conclusion of these authors as to the value of the test in actual practice is of much interest. They believe that a positive reaction is of value only when it agrees with other findings, in which case it is of value and points to a favorable prognosis. But when the reaction is negative in the presence of true fungous infection, the prognosis is poor. When both the reaction and the examination for fungi are negative, it is fair to assume that the eruption is nonmycotic. This latter statement is of particular importance in occupational dermatoses.

Muskatblit [18] has found that the clinical diagnosis was more frequently corroborated by the trichophytin test than by the laboratory examination. In clinically mycotic cases, the test showed positive reactions in 60.3%, whereas laboratory confirmation was positive in only 39.7%. This seems like a low percentage for laboratory confirmation.

The use of trichophytin in the treatment of the mycoses is as yet unsatisfactory. When the case histories and the data of some of the highly enthusiastic reports are analyzed, it appears that the optimism of the writer is not justified, or at least it is not entirely supported by the evidence submitted.

The case against the use of trichophytin in the treatment of the dermatomycoses was well presented in 1935 by Traub and Tolmach.[19] In a series of 135 cases, using a commercial preparation in some of the cases, a pellicle preparation of their own in others, and a combination of the two in still a third group, they found apparent cures in 14 cases. Some of the patients showed early recurrence, and some of the so-called cures were questioned. In 63 cases no change was observed, or the patient's condition was made worse. The authors concluded that trichophytin had little, if any, effect on the course of the treatment.

The results of the use of vaccines, which differ from trichophytin in that toxic products, together with fungous elements, are utilized in treatment, were reported in 1938 by Tolmach and Traub.[20] Using three different kinds of vaccine on 60 patients with dermatophytosis with and without ids and tinea capitis, they found that 60% of the patients were entirely uninfluenced, with 9% apparently cured. The authors believed that both the cure and improvement of the cases were subject to question and that vaccine treatment of dermatophytosis is not yet practical.

The work of Peck and his collaborators holds much of promise in the solution of the problems involved in the use of trichophytins. Various observers have maintained that the skin reactive factors in trichophytin were not necessarily identical with the therapeutic or immunizing principle. With this idea in mind, daFonseca prepared two different types of trichophytin extract, one called "dermatocofitin," containing only the skin test principle, and the other the "clasovaccine" or therapeutic principle, with no skin reactive factor present. Peck[21] attacked the problem by the study of pH cultures of T. gypseum in fluid Sabouraud medium. Starting from both the acid and alkaline side, he found that the pH of cultures of T. gypseum tended to go up or down the scale until a pH of 8.6 was reached, after which there was little fluctuation. In the period of rise there was an increase in skin test principle, whereas below a pH of 4, the reverse was true. By means of control and determination of pH, it was found possible to separate the skin test principle from the desensitizing fraction. The desensitizing trichophytins thus produced were found to be extremely effective in producing rapid desensitization in suitable patients without any local or focal reaction. The total nitrogen content of the trichophytin bore no relation to the amount of the skin test factors present in the bouillon.

Miller, Stewart, and Kimura,[22] however, attach much importance to the nitrogen content and accept the opinions of Bloch and his co-workers that this determination is the only method known at present for the standardization of trichophytin. Goodman and Marks[23] and Traub and Tolmach[20] are of the same opinion.

After considerable experience with trichophytin and oidiomycin as diagnostic and therapeutic aids, I have abandoned both as being of little value.

MYCOTIC INFECTIONS

In my early work with the mycotic infections of the hands and feet, I was influenced by Sabouraud who gave me the impression that all such cases were due to E. inguinale, or E. floccosum as it is known today. Therefore, only that organism was considered in the first series of cultures reported, although the Kauffman-Wolff organism was mentioned. However, in the second paper read in 1921, I reported the findings of 18 cultures of E. inguinale in a series of 103 cases and when the six cases previously reported are added to this number, approximately 20% had cultures of E. floccosum. In 36 cases the white organism was grown, and the addition to this number of the four previously reported cultures gave approximately 33% positive cultures for T. interdigitale, or T. gypseum as it is known today.

In view of these early findings of mine when I was groping along, it is interesting to note that Hopkins and his co-workers[24] in an intensive study of troops at Fort Benning, Ga., from 1942 to 1945 found T. gypseum in 47%, T. purpurium in 36%, and E. floccosum in 17% of the cases examined. Later Burke and Bumgarner[25] in a survey of 1,000 veterans found T. gypseum in 64%, T. rubrum in 34%, and E. floccosum in only 2%. Also in 1949, the same authors[26] reported the results of a study of 1,000 veterans with a service diagnosis of mycosis. In this series T. gypseum was found in 59.3%, T. rubrum 32.7%, and E. floccosum in 2%, and Candida albicans in 6%.

The gradual decrease in the number of positive cultures for E. floccosum is apparent in my own work, and the question has arisen in the past as to whether T. gypseum may not be the degenerative form of E. floccosum.

Sabouraud has said that two pathogenic fungi are never found in the same person. However, I have records and photographs of numerous cases in which one fungus was cultivated from the toes and another from the crotch. In an elderly man, cultures were made from the same scales from the inguinofemoral folds. The colony of E. floccosum could be seen at the bottom of the tube, and when subcultures were made, the two organisms coexisting could be definitely identified.

I am particularly interested in the findings of Burke and Bumgarner[26] in 41 patients, all white men, with service diagnoses of otomycosis. In only five were fungi found. In all five, a species of Aspergillus was cultivated.

Of all of the fallacies fastened on the medical profession by constant repetition in print and by word of mouth, the idea that all inflammatory conditions in the auditory canal are mycotic is about the most fallacious. In hundreds of cases with the history of a diagnosis of fungous infection of the ear and treated as such, I have yet to see a patient who had had a microscopical examination for a fungus made, much less a culture. In all the many cases seen in private practice, I have seen only one due to Aspergillus niger. My experience with these cases led me to present a paper on the subject before the Section on Dermatology at the Kansas City, Mo., meeting in 1936. Attention was called to the fact that these cases are due usually to microbic rather than to fungous infection and that the Streptococcus can frequently be grown. These findings have been corroborated by investigators who worked with naval personnel in the Pacific.

S. N., male aged 39 years. Fungous infection of the nails for many years. After daily applications of ammoniacal silver nitrate solution for three months, the nails were trimmed showing the thin black line of the nails but also showing the perfectly white thickened nail bed with no evidence of penetration by the ammoniacal silver nitrate solution. In this nail bed material, fungi were demonstrated microscopically and were viable.

Fungous infection of the nails is to me, as yet, an unsolved problem. The whitish involvement of the surface of the nail is usually amenable to local applications, but

when the nail bed is involved, every known method of treatment may fail. Surgical removal is usually followed by recurrence of infection in the newly formed nail. The roentgen ray is of no value. Iodine in goose grease and other liquids may be useful. Double strength benzoic and salicylic acid ointment may be of value, and the application of a carefully fitted 40% salicylic acid plaster may give results.

My therapeutic results with the use of ammoniacal silver nitrate solution in fungous infections of the nails as advocated by Nickerson and White[27] have amounted to nothing. I have treated a sizable number of cases with negative results. After four months of daily applications of ammoniacal silver nitrate solution to the nail of the big toe, the nail bed remains white, and numerous viable mycelia are present. I have other similar cases (figure).

INTRAVENOUS USE OF PITUITARY ADRENOCORTICOTROPIC HORMONE (ACTH)

A REPORT ON ITS ADMINISTRATION IN TWENTY-FIVE PATIENTS

William Mandel, M.D., Michael J. Singer, M.D., H. Rudolph Gudmundson, M.D., Lester Meister, M.D.
and
F. W. S. Modern, M.D., Long Beach, Calif.

Gordon[1] has recently reported that the increase in response in the eosinophil count and in the urinary excretion of steroids in subjects who received pituitary adrenocorticotropic hormone (ACTH) by continuous (12 hour) intravenous infusion was twentyfold when compared to response from the administration of the same dose of the drug given in a single intramuscular injection. With this knowledge, we administered pituitary adrenocorticotropic hormone intravenously to 25 patients with diseases generally known to be responsive to the drug. This report summarizes our experience with this form of treatment. We were particularly impressed by the effectiveness of small amounts of the medication when given by this route, for the doses employed were only fractions of the amounts that had previously been required by intermittent intramuscular injection.

MATERIALS AND METHODS

All patients studied were hospitalized and under our supervision during the entire treatment period. Blood pressure and weight were recorded daily. Urinalysis, complete blood count, erythrocyte sedimentation rate, total eosinophil count, electrocardiogram, serum sodium, serum potassium, serum chloride and the carbon dioxide combining power of the plasma were determined weekly. When indicated, these studies were done more frequently. In patients with rheumatoid arthritis and spondylitis the range of active and passive motion was determined weekly. All patients were on diets containing approximately 2 Gm. of sodium chloride a day. Pituitary adrenocorticotropic hormone[2] was administered each day in one of three ways: by continuous intravenous infusion for eight to 20 hours, by intermittent intravenous injection every six hours and by continuous intramuscular drip. With one exception, all patients received pituitary adrenocorticotropic hormone by continuous intravenous infusion during a portion of their treatment period. Administration by intermittent intravenous injection and by the continuous intramuscular drip method were employed mainly for the purposes of comparison with the continuous infusion technique. Prior to and during the treatment period several patients were given intravenous infusions to which medication was not added. When given over the 20 hour period the infusion was started at 11:00 a. m. and discontinued at 7:00 a. m. of the following day. This allowed time for necessary laboratory work and for the patient's self-care. When given continuously for eight to 12 hours the night hours were originally included because of the known diurnal variation in adrenal cortical activity.[3] In subsequent patients the daytime hours were included so that comparisons could be made with administration during the night hours. The medication for each patient was kept separately. Initially the daily dose of pituitary adrenocorticotropic hormone used was 20 mg. This amount was reduced by 2.5 to 5 mg. a day at three to six day intervals. If relapse occurred the dose was increased by the same amount. Subsequent patients were started on 5 to 10 mg. a day with gradual reduction in dose for maintenance purposes. The daily dose of pituitary adrenocorticotropic hormone was dissolved in a 5 per cent solution of glucose in distilled water containing 0.2 per cent potassium chloride.[4] When given for the 20 hour period the medication was added to 1 or 2 liters of fluid. When given for eight to 12 hours the medication was added to either ½ or 1 liter of fluid. Ten cc. of 1 per cent procaine hydrochloride (novocain®) were added to each liter of the intramuscular drip, and 300 TR (tubidity-reducing) units of hyaluronidase[5] were deposited at each site of injection. Transient local edema and induration occurred frequently with this procedure. By attaching the infusion bottle to a wheelchair most patients on intravenous infusion became semiambulatory and were able to sit in the chair or to walk behind it.

15 T. J.	37	M	Rheumatoid arthritis, mild; psoriasis, severe	A	7	5-10	8	60	+++	Acne; moon face	The intravenous infusions followed a course of intramuscular administration of ACTH; the remission was maintained, and there was further, though still not complete, disappearance of the psoriasis
16 N. K.	35	M	Bronchial asthma; angioneurotic edema	A	5	5-15	9	47	++++	None	Symptoms recurred during the first three days during the interval in which the infusion was not running; these subsided shortly, when the therapy was resumed
17 M. P.	63	F	Bronchial asthma	A	8	3-20	11	88	++++	None	There was no response to the usual antiasthmatic measures, but rapid improvement occurred with administration of ACTH
18 L. L.	30	M	Bronchial asthma	C	5	8	8	40	++++	None	Refer to case report
19 R. A.	29	M	Bronchial asthma	B	2	5	5	10	++++	None	Similar to case 17
20 W. G.	57	M	Chronic disseminated lupus erythematosus	A	3	10-20	17	50	+++	Marked confusion	Refer to case report
21 C. G.	23	M	Polyarteritis nodosa	A	26†	10-20	17	445	++++	Weight gain; euphoria; personality change	A previous course of ACTH resulted in a response evaluated as ++; the total dose given was 1,500 mg., and this was administered for 15 days; relapse tended to occur when placebo infusions were substituted for the infusions containing ACTH
22 M. G.	30	M	Rheumatic fever, acute recurrent	A	13	10	10	130	+++	Gastrointestinal bleeding	Refer to case report
23 O. T.	59	M	Scleroderma	A	3	11	11	32	0	Restlessness; nausea and epigastric distress	When intravenous medication was resumed the same symptoms recurred and were severe enough to discontinue further treatment
24 J. G.	64	M	Neurodermatitis	A	11	3-20	9	91	++++	None	The improvement was dramatic in a disease which had been very resistant to treatment for many years
25 E. H.	28	M	Eczematoid dermatitis, angioneurotic edema	A	8†	5-20	12.5	90	+++	None	Substitution of placebo therapy on the third day resulted in initiation of relapse which was controlled by resumption of infusions of ACTH

---

* ACTH was administered in one of four methods: by continuous intravenous infusion for 20 hours each day (A), by continuous infusion for 8 to 12 hours each day (B), by intermittent intravenous injections every six hours (C) and by continuous intramuscular drip for 20 hours each day (D). Comments under Response, Reactions and Remarks refer to the entire period of treatment and not to just one portion.

† The treatment period has not been completed as of this writing. ‡ The clinical response was graded from 0 (no response) to ++++ (disappearance of disease activity).

Pituitary adrenocorticotropic hormone was given intravenously to 25 patients for from two to 26 days. Twelve of the patients had rheumatoid arthritis. Of these 12, five had associated diseases: psoriasis in three, regional enteritis in one and conjunctivitis and urethritis (Reiter's syndrome) in another. Three patients had rheumatoid spondylitis, and four had bronchial asthma. Of the remaining six, one each had lupus erythematosus, polyarteritis nodosa, scleroderma, rheumatic fever, neurodermatitis and eczematoid dermatitis. The case reports are summarized in the accompanying table. Five cases will be described in greater detail.

REPORT OF CASES

CASE 1 (see table).—W. B., a 31 year old white man, had had chronic progressive rheumatoid arthritis involving most of the peripheral joints for the past seven years. He had had numerous hospitalizations and had received typhoid vaccine, desoxycorticosterone acetate, gold, salicylates and physiotherapy without definite benefit. Prior to the intravenous administration of pituitary adrenocorticotropic hormone, he had received three courses of the drug given by intramuscular injection at six hour intervals. In the first treatment 40 mg. were given daily for 12 days, a total of 480 mg. There was no clinical improvement or any significant change in any laboratory studies. Four hours after the first dose of pituitary adrenocorticotropic hormone (25 mg.) the eosinophil count had dropped 50 per cent. Two months later a second course of pituitary adrenocorticotropic hormone was given intramuscularly over a 12 day period. The total dosage was 1,000 mg., with the daily dose being 80 to 100 mg. There was moderate relief of pain, and the tenderness and swelling of the affected joints decreased. The sedimentation rate remained elevated. The total eosinophil count dropped more than 50 per cent. The patient relapsed within four days after the last dose of pituitary adrenocorticotropic hormone. One month after relapse the drug was started again, 100 mg. being given daily for 15 days. The response was similar to that which followed the previous course. The mode of administration was then abruptly changed to continuous intravenous drip given daily for 20 hours. Twenty mg. of pituitary adrenocorticotropic hormone were given daily for the first two days. Within 24 hours further improvement occurred, and in 48 hours the patient was free of joint pain and swelling. After 48 hours 20 mg. of the hormone were administered by intramuscular drip. On the next day he began to show mild relapse. He was again placed on daily continuous infusion of the drug, with 10 mg. being administered for five days, and then the dosage was reduced to 5 mg. a day for three days. Within 24 hours he had regained the previously noted improvement. The total eosinophil count, which was 121 cells per cubic millimeter before the intravenous mode of administration, fell to less than 11 cells per cubic millimeter. The sedimentation rate fell and was normal on the seventh day. On the thirteenth day the dose was decreased to 3 mg. daily for two days, at which time a mild relapse occurred. The daily dose was then raised to 5 mg. for four days, and within 24 hours the symptoms disappeared. One of the patient's greatest difficulties had been immobility of the mandibular joints. These loosened sufficiently so that dental care could be given for the first time in several years. Medication was stopped for four days, during which time a mild relapse occurred. Pituitary adrenocorticotropic hormone was then given by intermittent intravenous injection, 1 mg. being injected every six hours. There was some improvement, but on the second day headache and chills developed, and the temperature rose to 104 F. The temperature returned to normal within 24 hours. Three days after the pyrogenic reaction he was feeling well. At the present writing, three weeks since treatment was stopped, he has remained in 70 to 80 per cent remission.

Comment.—This case is representative of many patients treated in this series. The response to the intravenous form of administration was more rapid in onset and the improvement more complete than that occurring after administration of larger amounts of the drug given intramuscularly.

CASE 14 (see table).—W. F., a 40 year old white man, had had rheumatoid arthritis and psoriasis for seven years. On admission he had painful swollen knee, ankle and finger joints with moderate limitation of motion. He also had an extensive psoriasis. He was given a total of 2,500 mg. of pituitary adrenocorticotropic hormone by intermittent intramuscular injection every six hours during a 25 day period. The range of joint motion increased 50 per cent. There was decrease in the pain and swelling of the affected joints. The skin lesions cleared, although a few patches of psoriasis persisted. Facial acne and mild systolic hypertension occurred. The sedimentation rate did not return to normal. There was a 50 to 60 per cent fall in the eosinophil count. The patient was then started on oral cortisone, receiving a total dosage of 1,400 mg. throughout 18 days. There was recurrence of pain and swelling in the joints, and the skin lesions spread during the treatment. At this time pituitary adrenocorticotropic hormone was resumed, 5 mg. being given by intermittent intravenous injections every six hours for four days. Within 24 hours the pain and tenderness decreased. Mobility in the joints increased. On the fifth and sixth days 10 mg. of the hormone were given by continuous intravenous infusion over a 20 hour period. Five mg. were administered on the next two days, then 2 mg. daily for three days and finally 1 mg. daily for the last three days of treatment. Within 24 hours after starting continuous intravenous infusion further improvement occurred. Within 72 hours the patient felt better than he had during any of the previous treatment periods. He was able to walk without difficulty, and there was full return of strength in his hands. The skin lesions began to clear and at the end of the treatment period were no longer present. Reactions which occurred during treatment included facial acne, weight gain, moon-shaped face and a left foot drop. It is not known whether this neurological lesion is in any way related to the medication employed. The eosinophil count fell to less than 11 cells per cubic millimeter. An attempt is being made to keep this patient in remission by intravenous doses of pituitary adrenocorticotropic hormone given at weekly intervals.

Comment.—In this case the response to continuous intravenous administration of the drug was more marked than with intermittent intramuscular injections, intermittent intravenous injections or oral cortisone. The possibility of maintenance therapy by periodic intravenous infusions of the hormone is being explored.

CASE 18 (see table).—L. L., a 36 year old white man, had a one year history of bronchial asthma which was becoming increasingly severe. Because of refractoriness to the usual antiasthmatic measures he was given a six day course of pituitary adrenocorticotropic hormone. This was administered by intramuscular injections at six hour intervals. The average daily dosage was 125 mg., with the total being 760 mg. He responded rapidly to this medication. The vital capacity, which was initially 37 per cent of normal, rose to 90 per cent of normal. His appetite increased, and he felt better than he had for several months. After discontinuance of medication he remained well for several weeks but then relapsed and was rehospitalized. A week of conventional treatment was again ineffective, and he was started on intermittent intravenous injections of the hormone, 2 mg. being given every six hours for five days. He responded in the same manner as he had before. The total dose of the drug given was 40 mg.

Comment.—This case was the only one in this series in which the patient did not receive pituitary adrenocorticotropic hormone by continuous intravenous infusion. Had this route been tried it is likely that the response would have been just as satisfactory with even smaller doses. This report shows the practicability of the use of the hormone given intravenously in acute disease states. The total dosage used was $\frac{1}{20}$ of that given by intermittent intramuscular injection.

CASE 20 (see table).—W. G., a 57 year old white man, had had disseminated lupus erythematosus for two years. He had received three courses of pituitary adrenocorticotropic hormone therapy, each consisting of 2,500 mg., given over a three week period. The medication had been given intramuscularly at six hour intervals. The daily dosage was between 80 and 100 mg. Within 48 hours after onset of each course of treatment he was clinically improved. His appetite increased; a sense of well being prevailed, and pain decreased. The eosinophil count fell to 40 to 60 per cent of pretreatment levels. There was no significant change in other laboratory studies. The sedimentation rate remained elevated. Remission could be maintained only by high doses, for when the dose was lowered or treatment was stopped the patient promptly relapsed.

One month after the last course of treatment the hormone was started by continuous intravenous infusion. Twenty mg. were given daily for two days. On the third day the dose was reduced to 10 mg. Within 24 hours improvement similar to that with intramuscular therapy occurred. After 48 hours the improvement increased and was more noticeable than with any previous courses of treatment. The medication had to be discontinued on the third day because of the sudden onset of extreme restlessness and confusion. This lasted several hours. The eosinophil count had fallen from a resting value of 154 to less than 11 cells per cubic millimeter. Within three days after stopping administration of the hormone, the patient relapsed to his former state. He refused further medication if given by the intravenous route.

Comment.—Pituitary adrenocorticotropic hormone given by continuous intravenous infusion produced more rapid onset of improvement, as well as greater response, than had occurred with three previous courses of the drug given intramuscularly. The treatment had to be stopped because of the onset of toxic symptoms. This had not occurred previously. Treatment using smaller doses was not resumed because of the patient's refusal.

CASE 22 (see table).—M. G., a 30 year old white man, had had recurrent acute rheumatic fever. His complaints were those of severe precordial pain, cough and shortness of breath of several days duration. In the past he had been successfully treated for subacute bacterial endocarditis. On this admission the patient was acutely ill. A friction rub was heard over the entire precordial area. Diastolic and systolic murmurs were audible over the aortic area. There was prominence of the left cardiac border by x-ray, and fluid was present in the right costophrenic angle. Pituitary adrenocorticotropic hormone seemed indicated because of the gravity of the patient's condition.

The hormone was given by continuous intravenous drip for 13 days. Ten mg. were given each day. Within 24 hours clinical improvement had occurred. The friction rub disappeared by the third day. At the same time the temperature and pulse returned to normal. The patient continued to do well until the tenth treatment day, when he began to complain of epigastric distress. On the thirteenth day he suddenly passed a large tarry stool and went into shock. He recovered gradually under appropriate treatment. When questioned he remembered having had similar epigastric distress, although he had no knowledge of previous bleeding. Treatment with the hormone was not resumed.

Comment.—This patient was treated with pituitary adrenocorticotropic hormone by continuous intravenous infusion for 13 days. He received a total dosage of 130 mg. of the drug. On the thirteenth day of treatment massive gastrointestinal bleeding, which was most likely due to a peptic ulcer, developed. Gastrointestinal bleeding has been known to follow intramuscular injection of the hormone. This report emphasizes the dangers that are inherent in the use of the drug when any effective route is employed.

RESULTS

After our early experience with the intravenous infusion of the hormone, daily dose levels of 5 to 10 mg. were selected for use in further treatment. All patients responded adequately to these doses. Relapse did not occur in any patients during the period of treatment. All patients who were treated again responded in a fashion similar to, or even more rapid than, their response to the initial treatment. Many patients could be maintained on daily doses which were smaller than 5 mg. It was our impression that the critical level was represented by a daily dose of between 2.5 and 5 mg. Patients who could be maintained on these levels often remained in remission for varying periods of time when treatment was stopped. Those patients who required higher daily maintenance doses often relapsed promptly when medication was discontinued. Undesirable reactions occurred more frequently when higher daily doses of pituitary adrenocorticotropic hormone were employed. The only response to placebo injections or infusions was mild subjective improvement. Relapses occurred in three patients when placebo therapy was substituted for intravenous infusion of the hormone.

The response to the continuous infusion of a single dose of the drug during each 24 hour period was roughly proportional to the length of its administration. This was demonstrated in case 11 (see table), for with the same daily dose of pituitary adrenocorticotropic hormone the 20 hour infusion was more effective than the 12 hour infusion, which in turn was more effective than intravenous injections every six hours. Many patients responded satisfactorily to continuous intravenous infusion given for eight to 12 hours each day. In spite of the reported diurnal variation in adrenal cortical activity there did not appear to be any marked differences, whether the infusions were given during the day or the night. In fact, in a few patients the daytime administration appeared somewhat superior.

Ten patients had prevously received the drug in intermittent intramuscular injections. In these the response to intravenous infusion of the hormone was usually more prompt and complete. Remissions after cessation of intravenous treatment were generally more prolonged than those after a course of intramuscular injections. Intermittent intravenous administration appeared to be more effective than intermittent intramuscular injections; continuous intravenous infusions were more effective than continuous intramuscular drip.

Most patients showed a distinct increase in appetite during treatment. The low salt diet was accepted readily. The weight gained was usually lost subsequently, although several patients maintained a gain of 907 to 2,268 gm. (2 to 5 lb.) when treatment was discontinued. The eosinophil counts and the sedimentation rates fell in all patients. Eosinophil counts of less than 11 cells per cubic millimeter were common (i. e. none seen). The change in the eosinophil count and in the sedimentation rate occurred earlier and was more marked in the patients treated with continuous intravenous infusion of pituitary adrenocorticotropic hormone than in those treated with intramuscular injection. No significant alteration was seen in the red blood cell count, the hemoglobin level or the serum proteins. A polymorphonuclear leukocytosis occurred in the majority of patients. Two patients developed transient hyperglycemia and glycosuria. Hypokaliemia did not occur.

Medication was interrupted in seven patients because of undesirable reactions. In three of these treatment could not be resumed. The patient in case 20 refused further treatment, the one in case 22 had severe gastrointestinal hemorrhage, and in case 23 (see table) the same untoward symptoms recurred with subsequent treatment. Common complaints during the first few hours of infusion were flushing of the face, a feeling of tightness across the chest and a sense of fullness in the abdomen. It was our impression that when smaller volumes of fluid were administered these complaints became less frequent. Symptoms and signs suggestive of Cushing's syndrome, such as acne, moon-shaped face, fluid retention and hypertension, were seen in many cases. These tended to disappear with reduction in dose and interruption of treatment. Many patients exhibited varying degrees of euphoria. Pyrogenic reaction occurred in three patients who were receiving intermittent intravenous injections of pituitary adrenocorticotropic hormone.[6] These reactions did not recur with subsequent infusions. It is uncertain whether the left foot drop that developed in case 14 was in any way related to use of the hormone.

COMMENT

The response to the hormone given over the 24 hour period depends on the amount, the route and the frequency of administration. Heretofore the daily amounts have varied from 40 to 160 mg. at onset of treatment, with reduction to maintenance doses of between 10 and 20 mg. a day. The route of administration has been the intramuscular one. Injections have been given at four to 12 hour intervals but are almost routinely administered every six hours. When the total daily dose is subdivided and given at more frequent intervals there is a greater response, as judged both by clinical improvement and by laboratory tests.[7]

Attempts have been made to increase the effectiveness of the drug by alterations in its plan of administration.[8] Efforts have been made to prolong its action so that fewer injections would be required. A long-acting form of pituitary adrenocorticotropic hormone (adactar®), which is prepared by adsorbing the hormone onto a colloidal aluminum phosphate carrier, represents such a product. This material, given once daily, produced adequate responses, though local reactions limit its usefulness.[9]

Although the hormone has been used clinically for several years there has been little mention made of the possibilities of its intravenous administration. Some reasons for this may have been the impurities present in the earlier products, the potential hazards of foreign protein therapy and the belief that administration by this route would offer no advantages over the more convenient intramuscular route. Moreover, literature supplied by the manufacturer caution against its intravenous use.

In 1948 Sayers and associates[10] described the fate and metabolic effects of pituitary adrenocorticotropic hormone given intravenously. Single doses of 50 and 100 mg. were given intravenously, in 200 ml. of saline over a one-half to one hour period, to two adult men. The only untoward reaction was mild chill and fever in one subject. Within two hours after administration the plasma content of the hormone had returned to its preadministration level. The maximum activation of the adrenal cortex as measured by the metabolic response occurred by the third hour and disappeared by the end of the sixth. Gordon, as we pointed out, was able to show a twentyfold increase in response to pituitary adrenocorticotropic hormone when a given dose was administered intravenously over a 12 hour period, as compared with administration of the same amount by a single intramuscular injection.[1]

Our experience has shown that by the simple expedient of changing from intermittent intramuscular injections to continuous intravenous infusion much smaller amounts of the hormone were needed to produce effective responses. Reasons for these differences are not known, but it is of interest to speculate on possible explanations. The hormone disappears rapidly from the blood stream after intravenous injection.[11] In vitro incubation of the drug with plasma, kidney or liver tissue results in inactivation of the hormone. After injection of pituitary adrenocorticotropic hormone labeled with I^{131} the adrenal cortex was found to contain the highest concentration of the material of any organ in the body. Two hours after injection the labeled material was no longer detectable in the adrenal cortex.[12] Inactivation of the hormone by muscle enzymes has been demonstrated by Dr. C. H. Li.[13] These data suggest that local destruction of the hormone occurs in muscle, that the disappearance rate of pituitary adrenocorticotropic hormone from the blood stream is very rapid and that the drug is selectively absorbed by the adrenal cortex. It is therefore reasonable to assume that the effectiveness of the hormone given intramuscularly depends on the rate and amount of effective material absorbed. The greater effectiveness of intravenous infusion is due to the more continuous adrenal cortical stimulation and to the fact that destruction does not occur at the injection site. Only minute amounts of the drug are required at any given moment to stimulate the adrenal cortex, e. g., 10 mg. of pituitary adrenocorticotropic hormone given over a 20 hour period supplies only 9 gamma of the drug to the blood stream each minute.

---

[6] Similar reactions were observed in two other patients, not included in this report, who were receiving the hormone by intravenous infusion. Pyrogenic reactions of this type are rare in this hospital. A check of the sterile needles supplied was negative for pyrogenic material. (We are indebted to Dr. L. L. Ely and the Baxter Company for performing these studies. We were reassured by them that kaladex® was nonpyrogenic.) Two of the five medication vials showed evidence of contamination. In one the solution was turbid and from the other a gram-negative rod was grown. Although not proven, it is likely that all the pyrogenic reactions were due to contamination.

[13] Cluxton, H. E., Jr.: Personal communication to the author.

The obvious advantage of the intravenous form of administration of the hormone is its relative economy. In addition, the therapeutic results were often more satisfactory than had been seen with previous intermittent intramuscular administration. Refractoriness did not occur in any of the treated patients. This suggests that the phenomenon of refractoriness to the drug by the intramuscular method may be in part related to the mode of administration. The intravenous administration of pituitary adrenocorticotropic hormone is highly practicable in those acute conditions that in the past have responded satisfactorily to relatively short periods of intramuscular treatment. Patients must be followed closely when this method of administration is used, for undesirable effects may occur more frequently and with greater rapidity.

SUMMARY

Pituitary adrenocorticotropic hormone (ACTH) was administered intravenously for periods of two to 26 days in daily doses of 1 to 20 mg. to 25 patients with a variety of conditions. The average daily dose employed was between 5 and 10 mg. given for eight to 20 hours a day. Comparison was possible in 10 patients with previous courses of intermittent intramuscular injections, while in the remainder our past experience with intramuscular therapy was used as the basis for comparison. The therapeutic results were equally as good or even better, with only $\frac{1}{10}$ to $\frac{1}{20}$ of the doses previously employed. No patients were refractory to the hormone when given by this method. There were no patients who relapsed while being treated with adequate doses. There were no patients who were refractory on subsequent treatment. Reasons for the differences in the dose required by the two modes of administration are discussed. The advantages and disadvantages of the intravenous administration of the drug are enumerated.

ADDENDUM

Since completing this report we have treated 80 additional patients with the hormone by intravenous infusion. The initial treatment has been concluded in all patients. The longest period of continuous treatment was 42 days (case 2). Three patients included in the report have been treated again. The accumulation of further data has tended to confirm the results cited in the report.

BODY TEMPERATURES DURING ANESTHESIA IN INFANTS AND CHILDREN

John A. Bigler, M.D.
and
William Otis McQuiston, M.D., Chicago

Fever, convulsions and death following surgery on children is a sequence of complications that has long been dreaded by surgeons and anesthesiologists. Dr. Isabella C. Herb[1] pointed out in "Abt's Pediatrics" in 1925 that operating room temperatures should be between 65 and 70 F., and that temperatures above this are exhausting to the patient. Although the staff at The Children's Memorial Hospital was conscious of this danger, our only preventive measures were the usual ones—such as light draping, cancelling of elective surgery on excessively hot days and ice packs following surgery if the temperature was noticeably elevated at the conclusion of surgery.

In the summer of 1947 we were suddenly jolted out of our complacency by two deaths due to postoperative hyperthermia.

REPORT OF CASES

CASE 1.—T. M., 1 year of age, was operated on for correction of webbed fingers. The day before surgery his temperature was 100.4 F. rectally. No reason for this slight elevation could be found. His rectal temperature the next day before going to the operating room was 98.8 F. The anesthesia was started at 9:35 a. m., and the operation was completed at 1 p. m. Ethyl chloride induction, followed by open drop ether, was used for the anesthesia. During surgery the anesthetist reported that the child was not doing well. The pulse and respiration rates were rapid, and there was profuse perspiration. Oxygen and intravenous fluids were administered. Following surgery the child was placed in an oxygen tent, the temperature in the tent being 76 F. The body was very hot, and the feet were cold. The pulse rate was 150 to 200, and the respiratory rate was 48 to 80 per minute. Death occurred at 2:45 p. m., when the rectal temperature was 108.5 F. At autopsy there was edema and congestion of the brain and leptomeninges, petechial hemorrhages throughout the brain and miliary tuberculosis only of the lungs, liver and spleen. The impression of the main cause of death was heat stroke.

CASE 2.—D. D., the second patient, was first operated on for a tracheo-esophageal fistula at the age of 3 days. The proximal end of the esophagus was brought out through the neck. The lower end was ligated, and a gastrostomy was done. On his last admission, at the age of just past 1 year, his temperature had fluctuated from 97.8 to 100.6 F. rectally. Anesthesia for anastomosis of the esophagus to the fundus of the stomach placed in front of the thorax was started at 1:35 p. m., and the operation was completed at 6:25 p. m. Anesthesia consisted of cyclopropane with oxygen administered by the to-and-fro technique. An adequate airway and gaseous exchange were difficult to maintain. At the end of the operation the temperature was 101.4 F. rectally, the pulse rate was 106, and the respiratory rate was 108. Three hours later the temperature was 108 + F. rectally. In spite of the patient being in an oxygen tent and ice packs, death occurred 12 hours later. Preoperative medication consisted of morphine, $\frac{1}{32}$ grain, and atropine sulfate, $\frac{1}{300}$ grain. At postmortem the essential observations were cerebral edema and congestion of the lungs, liver and adrenals.

Personal communications from other physicians in the Chicago area revealed other similar deaths of children in whom hyperpyrexia was developing during or

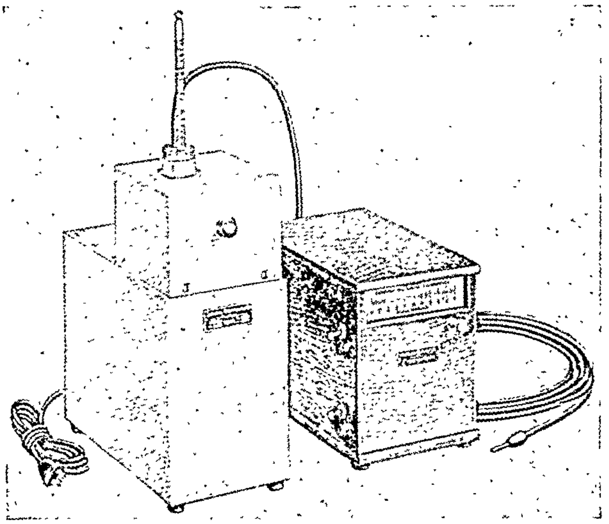
following surgery. Although there have been some studies of temperatures during anesthesia, the significance of fever and its control has not been sufficiently emphasized. Knight[2] reported in 1942 that hyperpyrexia is of frequent occurrence during prolonged operative procedures, and that it has a deleterious effect on the recovery period. He believed that the closed system of administering anesthetic gases tends to raise the patient's temperature. He developed a gas cooler to control the rise in body temperatures. Burstein and Mark[3] state that in the closed system the carbon dioxide absorber, especially of the to-and-fro variety, tends to warm the breathing mixture. They reduced the heat by using ice bags on the upper end of the to-and-fro cannister and the face mask. By this method the rise in body and skin temperature is minimized. Without ice bags and with a room temperature of 85 F. the rebreathing atmosphere rises to between 104 and 113 F. With ice bag technique the gas temperatures were between 83 and 87 F.



Thermo-electric clinical thermometer with constant temperature well, galvanometer scaled for reading degree of temperature and rectal insert.

We were unable to adequately control the body temperatures in children by cooling the gases in a to-and-fro absorption system. We have had no experience with gases cooled with the circle technique.

PROCEDURE

Rectal temperatures taken at the termination of surgery revealed that the majority of the children undergoing surgery had some elevation of temperature. It seemed desirable that continuous temperature recordings should be made. Consultation by Dr. Bigler with Dr. Marshall N. States and Dr. Harris M. Sullivan of the Central Scientific Co., of Chicago, resulted in their construction of a thermo-electric clinical thermometer that was safe to use when explosive anesthetic agents were being administered.

The apparatus consists essentially of a thermocouple, one junction of which is held at a constant temperature in a constant temperature well, the other junction being an integral part of the rectal insert. The thermocouple current is read on the scale of a galvanometer that is calibrated in degrees. The instrument is completely electronic, and there are no sparking points.

Until the spring of 1948 we were concerned chiefly with the causes and prevention of hyperthermia. The advisability of producing hypothermia for the purpose of decreasing the oxygen demand during operation on "blue babies" was discussed. Perusal of the voluminous medical literature on cold therapy, the effects of cold and local refrigeration anesthesia, led us to believe that hypothermia may be produced safely in adults, but we were unable to find any reports of the deliberate production of hypothermia in critically ill children. In fact, the literature abounds with reports on the conservation of body temperatures in children undergoing surgical procedures. However, because of the acute need of increasing the arterial oxygen or of lowering the oxygen demand in patients with critical hypoxemia, we decided to resort to hypothermia.

Case 3.—Thomas O., aged 3 months and 25 days, was admitted to the hospital in May of 1948 with marked cyanosis. He had begun to have spells of cyanosis at the age of 2 months. During these attacks, which lasted for about 30 minutes, he became semicomatose and blue-black in color.

It was the unanimous opinion of the cardiologists, surgeons and anesthesiologist that the infant would probably die on the operating table. But it was obvious that he was doomed without surgery. Therefore, it was decided to attempt an anastomosis.

Morphine, 1/60 grain, and atropine, 1/800 grain, were administered one hour before the operation. Cyclopropane was administered by the to-and-fro technique, and the infant was surrounded with ice bags. His temperature was lowered until it registered 96 F. rectally. Very little cyclopropane was needed for maintenance of the anesthesia. In fact, for more than 90 minutes the cyclopropane valve was shut off. On the completion of an anastomosis between the aorta and the pulmonary artery hot water bottles were applied. When the rectal temperature reached 96.7 F. the patient began to react, and cyclopropane was again administered for closure of the incision. The patient was awake when he left the operating room. The total anesthesia time was three hours.

Convalescence: After 24 hours the infant was removed from his oxygen tent. Phleboclysis was discontinued, and he was given a full formula by bottle. He was discharged on the fourteenth postoperative day after an uneventful recovery.

RESULTS

The normal rectal temperatures of infants and children are approximately one degree higher than the mouth temperatures. In our tables, for convenience, we used rectal temperatures of from 99 to 100 F. as normal and placed all temperatures in units of one degree. Two hundred and fifteen patients between 4 days and 13 years of age who underwent surgery were studied. Eight patients had a temperature of from 100 to 101 F. on arrival in the operating room.

CONTROL GROUP

The control group consisted of 89 patients who had no cooling and 22 patients who were cooled with ice bags after alarming fever had developed. Hence, it is obvious that in these 101 children the number in whom extremely high temperatures were developing would be more than the number indicated in chart 1. It is also probable that some temperatures would have exceeded

104 F. had not ice bags been used before the termination of surgery. Twelve of the 22 patients were in such critical condition that ice bags were used before their temperatures reached 102 F. We did not feel justified in jeopardizing any child for the purpose of a statistical study.

As can be seen in chart 1, 62.3 per cent of the children in the control group suffered temperatures above 100 F. Seven of these 63 children suffered temperatures of between 103 and 104 F., 15 of between 102 and 103 F. and 17 of between 101 and 102 F.

Of the 22 patients on whom ice bags were used, eight became normal or subnormal before surgery was completed. Of these, the temperatures were from 99 to 100 F. in three, 98 to 99 F. in three, 97 to 98 F. in one and 96 to 97 F. in one. The remaining 14 patients continued to have fever at the close of the operation.

In 41 patients with fever no ice bag cooling was used. Only five of these had a normal temperature, and one had a temperature of from 98 to 99 F. at the end of surgery. The other 35 continued to have fever. Although ice bag cooling of the patient was of some help, it was not as helpful as expected.

The normal and subnormal temperatures recorded in chart 1 were the highest temperatures recorded during surgery. Of those below 97 F., all but one were in infants under 6 months of age (chart 3). The exception was under 1 year of age. Of the 38 patients without some fever, only 20 were within the normal 99 to 100 F. range.

In this control group there was a spread of temperatures of from 93 to 104 F., or of 11 degrees.

ICE BAG COOLING

During the hot summer months ice bags were used on a number of surgical patients in an attempt to control the temperatures during surgery. This not only was disturbing during the operation but also was not particularly effective in controlling the fever in some patients. Twelve patients had ice bags packed around the body from the start of anesthesia. Of these, six (50 per cent) developed fever, two of from 103 to 104 F. and four of from 100 to 101 F. Of these six patients, body temperature was above normal at the end of surgery in four, normal in one and subnormal in one. Of the six with no fever, one was normal, two were from 97 to 98 F., and three were from 96 to 97 degrees F. at the termination of surgery. In two of the latter hot water bottles were substituted for the ice bags during surgery.

Because of this experience with ice bags, the development of a more easily controlled technique seemed advisable. A rubber mattress, measuring 19 by 24 inches, was constructed for us by the Davol Rubber Co. This mattress is compartmented in order to give it stability when it contains water. Inlet and outlet tubing at opposite corners facilitate the regulation of the mattress temperature by introduction of hot or cold water.

WATER MATTRESS GROUP

The water mattress was filled and in place on the operating table under the sheet. Each child was placed on the mattress before the induction of the anesthesia and surgical preparation. The temperature of the water in the mattress varied from tap water of 60 to 70 F. to ice water of 40 to 50 F. The temperature of the water was varied according to the age of the child, the room temperature and the degree of cooling desired by the anesthesist. For patients under 1 year of age ice water was not necessary at any time.

The water mattress was used with 102 patients. In 40 (39.2 per cent) the temperature rose above 100 F. rectally (chart 1). There were no patients with a fever over 102 F., in contrast to 24 in the control and ice bag groups. In only eight were the temperatures 101 to 102 F., and in 32 the temperatures were 100 to 101 F. The temperature was normal before the end of surgery in 25 of the 40 patients. It was below 100 F. in 15 minutes in two patients, in 30 minutes in 10, in 45 minutes in two, in 60 minutes in five, in 75 minutes in five and in two hours in one. Of these 25 patients, the temperature before the end of surgery was 99 to 100 F. in 17, 98 to 99 F. in three, 97 to 98 F. in three, 96 to 97 F. in one and 94 to 95 F. in one. In three the cool water was replaced with warm water when the temperatures became subnormal.

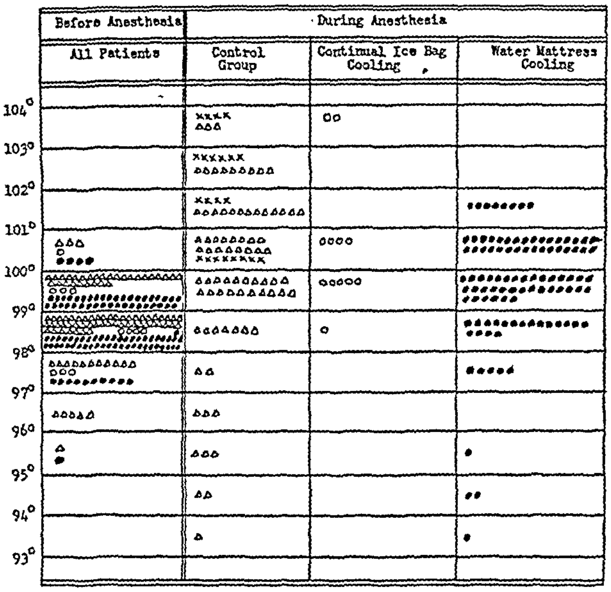

Chart. 1.—Highest temperatures recorded during anesthesia, with the explanation of symbols as follows: triangle, patient in whom no cooling method was employed; "x," patient in whom ice bags were used after rise in body temperature; open circle, patient in whom ice bag cooling was used continually, and closed circle, patient in whom water mattress cooling was employed.

Of the 63 cases with their highest temperatures normal or subnormal, as indicated in chart 1, those below 97 F. all occurred in infants under 1 year of age. Temperatures of from 97 to 100 F. were about equally distributed in the age groups over 1 year of age. Hot water replaced the cool water when the temperature became subnormal in 17 instances. In the mattress-cooled group the variation in temperatures was 11 degrees, but the fevers were not as high, and more cases fell within the normal or slightly subnormal range.

TEMPERATURES BEFORE SURGERY

In only eight patients was there an elevation of temperature before surgery. In one patient ice bags were used from the beginning of the anesthesia. The temperature was 101 F. before surgery and gradually came down to 100.4 F. in two hours at the end of the operation. Three patients with temperatures of 100.2, 100.6 and 101 F. had no cooling, and at the end of surgery, one and one-half to two hours later, they had fevers of 101.6, 101.5 and 103.4 F. The remaining three patients were cooled with the water mattress. The temperature before surgery was 100.2 F. in two patients and 100.8 F. in the third, but at the end of 45 minutes two were normal, and the third was 100.6 F. at the end of surgery, one hour and 40 minutes later.

ONSET OF FEVER

A temperature of over 100 F. was present in 109 of the 215 patients studied. In chart 2 the time of onset of the fever after the beginning of surgery is divided into 15 minute periods for the first hour and then into hourly periods thereafter. In 63 patients (57.8 per cent) the temperature began to rise above normal in the first 15 minutes, while 27 (24.7 per cent) did so in the next 15 minutes. This means that 82.5 per cent of the febrile patients began to develop a temperature within the first 30 minutes. It is apparent that something besides the actual surgery must influence the temperature.

Chart 2.—Time of onset of fever after start of anesthesia (only temperatures above 100 F. recorded), with the explanation of symbols as follows: *triangle,* patient in whom no cooling method was employed; *"x,"* patient in whom part time cooling was used; *open circle,* patient cooled through the continual use of ice bags, and *closed circle,* patient in whom water mattress cooling was employed.

PREOPERATIVE MEDICATION

In all but a few of the very young infants some preoperative medication was used. In patients a few weeks to a few months of age small doses of atropine were administered preoperatively. Between 1 year and 5 years of age the majority of the children received both morphine and atropine, while most of the children 5 years of age and older received morphine and scopolamine hydrobromide as preoperative sedation. Although it is generally believed that the belladonna group of drugs may cause fever, no relationship between these drugs and fever could be shown in this series. The old belief that morphine will tend to prevent fever [1] may be correct, but it did not prevent fever in over 50 per cent of the patients studied.

ANESTHESIA

The majority of the 215 patients studied were thoracotomies, usually for correction of a congenital heart lesion. These patients were almost routinely anesthetized with cyclopropane administered by a to-and-fro technique through an endotracheal tube. This may have had an influence on our observations; however, open drop ether, with and without oxygen insufflation under the mask, semiclosed, circle absorption and pharyngeal insufflation techniques were all used in various other types of surgery, and no definite influence on temperature elevation could be shown due to the method of administration.

AGE OF THE PATIENTS

The patients varied in age from 3 days to 13 years. The age of the patient had a very definite influence on the temperature during surgery. Below 6 months of age the infant tends to develop hypothermia—only one patient in this group had a temperature above 100 F. Between 6 months and 1 year of age, half the patients developed hyperpyrexia while one-half developed hypothermia. From 1 year to 13 years of age the children in the control group had an average temperature of 101 to 102 F., while the cooled group showed an average temperature of 100 F. The temperatures of all patients are shown in chart 3.

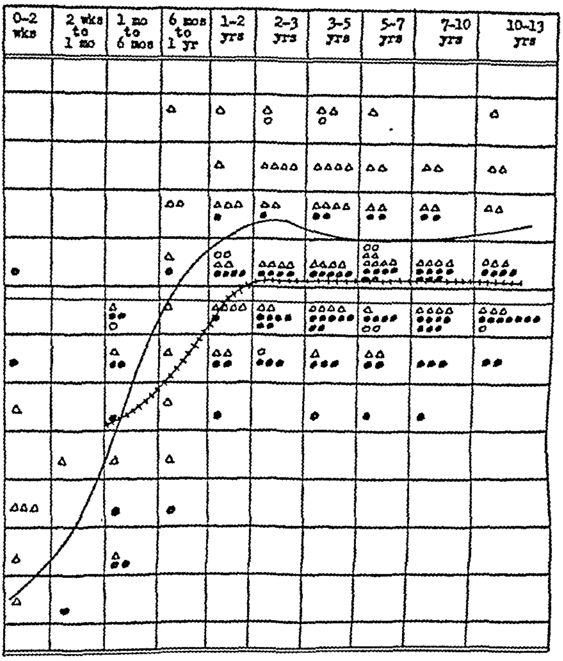

Chart 3.—Height of temperature during anesthesia relative to patient's age, with the explanation of symbols as follows: *triangle,* patient in whom no cooling method was employed; *open circle,* patient in whom ice bag cooling was used, and *closed circle,* patient in whom water mattress cooling was employed.

MONTH OF YEAR

There was very little difference between the number of patients with fever during the winter months and the number with fever during the hot summer months. Temperatures above normal were about equally divided between all months of the year, with the exception that the majority of fevers above 102 F. occurred between April and September. This same relationship holds true when one considers the operating room temperatures. We do not have air conditioning, and the temperature of the operating room varied from 69 to 88 F. Although there was a rise in temperature in some patients throughout this whole range, the majority occurred when room temperatures were between 76 and 82 F. The temperature about the patient must have been higher at all times due to the necessary draping (kept as light as possible), the number of people around the table and the operating room lights.

LENGTH OF SURGERY

In the group of patients studied each anesthesia lasted from 30 minutes to five hours. It can be seen in chart 2 that 82 per cent had a rise in temperature within the first 30 minutes. In most instances this will increase during the surgical procedure if cooling is not used.

RELATION TO TYPE OF SURGERY

As our thermo-electric thermometer was set up in only one of the operating rooms, the cases studied were rather selective. There were 154 cases, including great vessel surgery, anastomosis of the aorta and pulmonary arteries, division of patent ductus and excision of coarctation of the aorta. In 55 of these cases there was either no cooling or only ice bags about the patient after the temperature began to rise. In this group 41 (74.5 per cent) had fever above 100 F. Of the 11 patients who were packed in ice bags during the whole operation, six (54.5 per cent) had a temperature above 100 F. Of the 88 cases in which the cold water mattress was used, 37 (43.2 per cent) had some fever.

There were 11 cases of primary or secondary surgery of tracheo-esophageal fistulas. As would be expected when considering the age of these patients, only one suffered a temperature above 100 F. Mediastinal tumors and lobectomies made up 10 cases. Of the six patients without cooling, four suffered some fever, while the four who were cooled with the mattress maintained temperatures within normal limits.

Seventeen abdominal surgery cases included bowel surgery, abdominal and kidney tumors and bile duct atresia. Eight of 12 patients in the control group and two of five patients in the mattress-cooled group had some fever. There were four patients with inguinal herniorraphies in the noncooled group, all of whom had temperatures above 100 F.

In the control group there were 12 cases of surgery on bones and tendons, with fever in three patients, and one of three patients on whom skin grafts were applied had a fever. Of the remaining 16 miscellaneous patients, all in the control group, only one had fever.

TEMPERATURES AFTER SURGERY

It is always difficult to find the cause of postoperative fever and hence to rationalize on the relationship of temperatures during anesthesia and postoperatively. When no fever was present during anesthesia there was no significant difference in the number of children with fever within 72 hours postoperatively, whether cooled or not cooled. The average for each group was close to 50 per cent. The temperatures were 100 to 101 F. in 74 per cent, 101 to 102 F. in 20 per cent and 102 to 103 F. in 6 per cent.

In the control group of children with fever during anesthesia 77.5 per cent still had fever at the end of surgery, but only 50 per cent continued to have fever for 48 to 72 hours. In the mattress-cooled group the corresponding figures were 37.5 per cent and 42.5 per cent. There is little difference in the effect of cooling during anesthesia with respect to fever 48 to 72 hours postoperatively. Temperatures of over 101 F. were present in 42 per cent of the control group and 34 per cent of the water mattress group. All patients with anesthesia temperatures of 100 F. at the end of surgery had postoperative fever. This was generally higher in the noncooled group—one rising as high as 106 F.

There were 12 deaths in this group of 215 children. Four deaths occurred in cases of congenital tracheo-esophageal fistulas. Two of these were operated on at the age of 3 days (temperature of both being from 97 to 98 F.), one at the age of 4 days (temperature from 93.6 to 95 F.) and one 6 days old (temperature of 94.8 and 96 F.). All were in the control group; all had pulmonary infection before surgery, and all died shortly after the operation except one patient who died on the fourth day. Seven deaths occurred in the group with congenital malformations of the heart and one in the group with a double aortic arch. The temperatures were 91.8 to 95.6 F., age 7 months; 92 to 100 F., age 3 months; 92.8 to 94.6 F., age 6 months; 97.4 to 100.6 F., age 1½ years; 98 to 98.2 F., age 2¼ years; 98.4 to 98.6 F., age 2 months and 100 to 100.8 F., age 2 years. The two patients with temperatures over 100 F. were in the control group, and the rest were in the cool water mattress group. All died within 14 hours postoperatively, with the exception of two who lived two and six days respectively. None of these children were good surgical risks, and it was believed that the temperature during surgery had nothing to do with their deaths.

The postoperative course of the mattress group was generally better than that of the control group. All four patients with prolonged and unexplained fever were in the control group having fever during anesthesia. Major postoperative complications were about equally divided between the two groups and were usually related to the preoperative condition or to the immediate surgery. Major postoperative pulmonary infection occurred with approximately the same frequency whether or not the children were cooled during surgery. However, this series is too small to have statistical value on this point.

ANESTHETIST AND SURGEON

It is the opinion of both the technician anesthetists and the physician anesthetists who administer the anesthesia at The Children's Memorial Hospital that appreciably less anesthetic agent is required when the temperatures are subnormal. During surgery on "blue babies" subnormal temperatures seem to have a beneficial effect on the heart action. Exploratory operations on "blue babies" in which no anastomosis was possible had a mortality of 54.4 per cent in the uncooled group and a mortality of 14.4 per cent in the cooled group. Although the total number of these exploratory operations was only 18, the 40 per cent difference in mortality is probably significant.

The surgeons doing most of the operations have become very dependent on the information and control offered by the thermo-electric thermometer. Respirations and heart action are slower, and there is not as much perspiration and fluid loss. Hyperthermia can easily be recognized and controlled.

COMMENT

What the optimal temperature during surgery should be requires more study. From our own experience we feel that subnormal temperatures of between 95 and 97 F. are very satisfactory in selected cases. Burstein and Mark[3] state that without a temperature above normal the respiratory efforts remain effortless and of normal pattern. There is less laryngeal spasm, sweating is abolished and the pulse and blood pressure tend to remain normal. Crossman and Allen,[4] in writing on the treatment of shock by the reduction of body temperature, state that this causes a reduction of exudation and probably of toxin formation, a more liberal blood supply to the vital organs by constriction of the peripheral vessels and relief of anoxia by reduction of total metabolism. Temple Fay, in discussing the above paper, states that temperatures of 92 to 94 F. can be maintained for several days without ill effect. As body temperature is reduced to subnormal, more oxygen is had in solution in the blood, body tissue fluids and the cells themselves. Cellular metabolism is reduced, and therefore less oxygen is required. It has been found that for every degree of temperature change there is a change in metabolism of 7 per cent.

In reporting his experiments on the effects of hyperthermia and hypothermia in dogs, Prec et al.[5] reports that in the former there is increased oxygen consumption, reduced cardiac output and increased arteriovenous oxygen differential. The heart rate is increased, and the right auricular pressure falls. There is an increased demand by the tissues and vascular bed for blood. This, coupled with the reduced cardiac output, will lead to collapse unless vasoconstriction occurs. In hypothermia there is a decrease in oxygen consumption, respiratory and cardiac rates, and the blood pressure and the cardiac output fall.

Most of the above observations were true in our patients, as evidenced by less anesthesia, slower pulse and respirations, less perspiration and what appeared to us to be a better recovery period.

CONCLUSIONS

1. Temperatures of infants and children during surgery vary widely and should be carefully watched.
2. Infants under 6 months of age tend to develop subnormal temperatures during surgery, which so far we have not found harmful.
3. Fever during surgery developed in over 62 per cent of the children studied in this series between the ages of 6 months and 13 years when not cooled.
4. A cold water mattress is more efficient than ice bags in preventing fever.
5. Subnormal temperatures seem to be beneficial in certain selected cases.
6. Techniques, presently being perfected, for the simultaneous recording of heart rate, blood pressure, electrocardiograms, electroencephalograms and arterial oxygen saturation should be combined with temperature studies in children to give us added information on the effects of hyperthermia and hypothermia.

EXPERIMENTAL AND CLINICAL INVESTIGATIONS OF PERIPHERAL NERVE INJURIES OF THE UPPER EXTREMITIES

George Perret, M.D., Ph.D., Iowa City

Certain fundamental principles in the treatment of peripheral nerve injuries deserve re-emphasis from time to time. It has become a trite thing, but it is true that in the excitement connected with the immediate repair of a lacerated extremity tendons are mistaken for nerves and nerves are mistaken for arteries. The result is that a nerve may be sutured to a tendon or, even more frequently, a severance of the nerve trunk may not be recognized at all.

Early recognition of a peripheral nerve injury is the greatest single prophylactic measure that can be taken to insure a good result after surgical repair of an interruption in the continuity of a nerve trunk. Lesions of the median, ulnar, and radial nerves are the commonest of the injuries to the peripheral nerves in the upper extremities, and to these injuries must be added injuries of the brachial plexus. In general, it must only be kept in mind that an injury to a peripheral nerve produces the characteristic sign of a lower motor neuron lesion: that is, a flaccid paralysis, a loss of deep tendon reflexes and of sensation in all modalities, atrophy of muscles, and a reaction of degeneration on electrical stimulation.

The tests for lesions of the nerves most commonly injured in the upper extremity can be very simple. If a patient does not recognize a pin prick in the palmar surface of the distal two phalanges of the index finger it may be concluded that he has a lesion of the median nerve. If a patient does not recognize a pin prick in the palmar surface of the distal two phalanges of the little finger it may be concluded that he has a lesion of the ulnar nerve. The loss of sensation that follows a radial nerve lesion is so inconstant in the space bounded by the first metacarpal of the index finger and the thumb that it is better to rely on motor tests for the determination of a radial nerve injury. If a patient cannot extend his wrist with the palm flat on the table and drops the hand when the forearm is supported the patient has a lesion of the radial nerve. If the patient cannot make a cone with the tips of all his fingers and his thumb he has a lesion of the ulnar nerve. If a patient cannot make a complete fist by completely flexing the index finger or oppose the tip of the

Read before the Section on Orthopedic Surgery at the Ninety-Ninth Annual Session of the American Medical Association, San Francisco, June 30, 1950.

thumb to the tip of the index finger it may be concluded that he has a lesion of the median nerve. It must be obvious that if the lesion exists higher in the arm more peripheral muscles will be involved. The atrophy of the interosseous muscles—particularly between the space of the first metacarpal of the index finger and that of the thumb—that gives to the dorsal surface of the hand a skeleton-like appearance, with atrophy of the muscles of the hypothenar eminence, is characteristic of an ulnar nerve lesion. The paralysis and atrophy of the thenar muscles that place the thumb on a plane with the palm of the hand, thus producing an ape-like hand, is characteristic of a median nerve lesion.

The combination of nerves injured in a brachial plexus lesion is multiple. Therefore, it is quite confusing to speak of upper and lower types of brachial plexus injury. It is more accurate and more instructive to determine the muscles paralyzed and the nerves that innervate those muscles and thereby place the lesion accurately among the cords, trunks, or roots making up the brachial plexus.

In the presence of a peripheral nerve injury a second important principle prevails: the sooner the ends of the divided nerve can be united in accurate apposition by the finest suture material and the most meticulous technique possible the more successful will be the surgical end result. The ideal method of treating a divided peripheral nerve is to unite the severed ends directly by suture before neuromas are formed, before retraction has occurred, and before atrophy of muscles, fibrosis, and ankylosis of joints has taken place. It has been shown experimentally that muscle atrophy is less severe and ulceration of the skin less likely to occur if a divided nerve is united immediately after injury. There is abundant histological evidence to show that both in the animal and in the human regeneration is more perfect if the nerve ends are united before neuromas have occurred.

In my opinion it is better to unite divided nerve ends even in what may be considered a potentially infected wound than it is to leave the nerve ends disunited and allow neuromas to form and retraction to occur. Obviously, when neuromas form they must be resected with a loss of substance to the nerve trunk, thereby increasing the difficulty in bridging the gap between the divided ends of the nerve. Any nerve that is sutured under tension and in which stretching is necessary does not regenerate as successfully as one in which these conditions do not exist. With the advent of antibiotics there is no question in my mind that nerve ends should be sutured immediately, even though the wound may be potentially infected, provided careful debridement and mechanical cleansing of the wound is employed in the operating room in addition to the use of the antibiotic. It has been learned from experimental investigation that the local use of the sulfonamides does not interfere with the regeneration of a peripheral nerve. This does not mean that the local use of sulfonamides is superior to their systemic administration or to other antibiotics, but that if in the opinion of the surgeon the local use of sulfonamides is indicated he can be reassured that the resulting reaction in the tissues about the nerve will not handicap the regeneration of nerve fibers in the sutured nerve.

In certain conditions the repair of the nerve injury is of secondary importance to the overall treatment of the patient. A compound comminuted fracture of the humerus associated with a lesion of the radial nerve should be treated simultaneously with the peripheral nerve injury; but in such a condition, depending on the circumstances, the treatment of the nerve injury could be deliberately delayed. A large gap in continuity of a peripheral nerve must be classified and treated as a delayed peripheral nerve repair. If immediate end-to-end suture is not possible because of loss of nerve substance it is advisable to identify the proximal and distal nerve ends and anchor them as closely together as possible to surrounding muscle, fascia, or tendons by wire sutures. Thus they will be more easily found when definite repair of the nerve gap is undertaken. However, to deliberately delay the repair of a peripheral nerve injury in a clean lacerated wound without loss of nerve substance, even with the knowledge that the wound may become infected, is believed to be absolutely wrong.

It has been shown experimentally that every nerve injury is accompanied by a traumatic zone of degeneration. The result of this trauma causes the endoneurium to proliferate in the end of the central segment and to produce a disorganization in the usual pattern of nerve fiber degeneration. Traumatic degeneration and regeneration differ from wallerian degeneration and the following regeneration that occur when the nerve is separated from its cell of origin. An understanding of the simple mechanism of degeneration and regeneration and the microscopic changes that occur in a peripheral nerve fiber should prevent the repetition of certain practices doomed to failure and should be of great help to any surgeon who attempts to repair a peripheral nerve. It will make it obvious that the nerve should be handled with meticulous care and should be sutured with the finest material and needles available; that the sutures should always be placed through the epineurium of the nerve and not through the nerve trunk as a whole; that accurate apposition of the fascicles observed in the cross-sections should be attempted in order to restore the original pattern; that the passage of a metallic wire through a nerve trunk can only result in further degenerative products and in an obstruction to the regeneration of nerve fibers, and that the wrapping of the suture line with a metallic substance only interferes with the regeneration of nerve fibers because it prevents the ingrowth of blood vessels that help in the evacuation of decomposition products and the regeneration of nerve fibers. It may be concluded that, in my opinion, the use of metallic wire as stay sutures or as tension sutures or to unite divided nerve ends is not beneficial, and the wrapping of a suture line with any metallic substance is contraindicated.

The fourth principle deals with the treatment of what is usually called irreparable nerve lesion. If the severed nerve ends cannot be united because of a large gap in the continuity of the nerve trunk and if, therefore, end-to-end suture is not possible, other surgical procedures are available to insure a good result. It has been proved clinically and experimentally that nerve injuries produced by a stretch mechanism may be just as damaging as the direct severance of continuity by a sharp instrument. This is particularly true of brachial plexus injuries. Why, then, should a peripheral nerve be expected to regenerate if, in order to bridge a large gap, the nerve is stretched by the movements of joints adjacent to the site of injury? As a matter of fact, what is there to stretch in a nerve trunk? Nothing stretches; but structures rupture, and more degeneration results. Furthermore, it has been shown that ischemic necrosis of nerve fibers is caused by wide denudation of the nerve necessary for mobilization and may result in more extensive degeneration and delayed regeneration. To effect any result in a peripheral nerve injury in which there is a loss of substance such that an end-to-end apposition cannot be obtained, the following four possibilities may be considered: (a) the use of an autogenous graft; (b) the use of homogenous graft; (c) the shortening of the limb, and (d) the fixation of joints and the transposition of tendons of uninjured muscles. There is sufficient evidence available, both in experimental laboratories and the human patient, that autogenous grafts made of nerves of similar size to the injured nerve may be successful. Published and unpublished records of peripheral nerve patients show evidence of good functional results after the implantation of autografts. For accurate evaluation of the results it is of utmost importance that the patients be tested by the most exacting tests for determining the regeneration and recovery of a peripheral nerve injury, such as the movement of muscles innervated solely by the injured nerve and the return of pin prick sensation in the isolated area of supply to pin prick of the injured nerve. In my opinion, the use of multiple pieces of nerve graft of smaller caliber than the injured nerve—the so-called cable graft—is less successful in the human patient.

The opportunity to evaluate the use of fresh homogenous graft was lost during World War II when, in amputation and peripheral nerve centers, portions of the nerves of amputated extremities of one person were not used to repair large defects in the continuity of a peripheral nerve in another. A few such operations were carried out, but the results were evaluated after only six months, a time too short to even judge the return of function in a peripheral nerve injury that has been repaired by an end-to-end apposition. The use of autogenous and homogenous grafts have been studied experimentally, suturing a graft into place with fine silk or using the plasma clot technique. It should be mentioned that functionally and microscopically there appeared to be no advantage in using the plasma clot technique in preference to the silk suture method, except perhaps in those cases in which a very small nerve such as a digital nerve is injured and in which no tension in the suture line is present. Dr. Loyal Davis and I have used homogenous nerve grafts on patients followed six months to several years. The grafts were taken from the sciatic nerves of recently amputated extremities or from cadavers soon after death. The functional recovery after the use of homogenous nerve graft in man is distinctly inferior to that obtained under experimental conditions in animals. In all fairness, however, it must be stated that the delay of months or years before grafts were transplanted in all of these cases allowed the muscles to become severely atrophied and contracted, greatly limiting their recovery of function. Experience with homogenous grafts in man has shown that while the functional recovery is minimal and does not compare with that obtained with the use of autogenous grafts, the nerve grafts are not absorbed and are not reduced to fibrous bands.

In certain circumstances, such as fresh comminuted fractures, resection of one or two inches of the humerus has permitted successful end-to-end suture of severely injured nerves without handicapping the patients too severely. In long-delayed cases this method may be the only means of performing an end-to-end nerve suture and should be thought of when several nerves are involved. In the repair of brachial plexus injury resection of a segment or even the entire clavicle helps complete visualization of the plexus and is necessary for the end-to-end suture of the usually-retracted severed nerve segments.

Finally, there are those irreparable nerve injuries in which the nerve ends cannot be apposed and any type of graft is unsuccessful. In these the best possible method of obtaining the greatest amount of function in the affected extremity is the transplantation of tendons and the fixation of joints. As a matter of fact, I am inclined to have tendon transplantations performed after most high injuries of the radial, ulnar, and median nerves and in patients seen a year or several years after injury as an aid to functional recovery after nerve suture. This procedure helps to keep the joints from becoming ankylosed and the muscles contracted or overstretched. Hand and fingers are also kept in a better position of function.

Traumatic lesions that involve parts of the brachial plexus are not uncommon in civilian or military life. They may be the result of penetrating stab or bullet wounds or more commonly are produced by blunt trauma on the side of the neck with the head flexed far to the opposite side and the shoulder depressed. The chief factor is overstretching and traction on one or more components of the plexus produced by any means that force the head and the shoulder apart. The overstretched nerves may rupture at any point from the origin of the roots from the spinal cord to the most distal part of the plexus. Therefore, some fibers may be avulsed, others torn apart within the nerve trunks, and others overstretched. The resulting clinical symptoms are those of complete and incomplete anatomic or physiological lesions that cannot and should not be catalogued according to the early classification of brachial plexus injuries into the upper (Erb) or lower (Klumpke) types. I believe it is far more accurate and practical to determine the extent of the paralysis by careful, detailed examinations of the muscles and then place the level of the lesion by a knowledge of the innervation of those muscles. The progress of recovery could be followed more easily, and a final evaluation of the residual lesion could be made accurately.

The results of the surgical treatment of brachial plexus lesions are, on the whole, not as good as those of peripheral nerves. The distance between the site of the lesion and the muscles and skin involved makes nerve regeneration a slow and prolonged process. Therefore, the end results should not be evaluated finally for several years after repair. It is also obvious that neurolysis and nerve suture performed on the plexus cannot be done as extensively and accurately as on a single peripheral nerve trunk.

The contribution of Pollock and his associates—the question of electrodiagnosis in peripheral nerve injuries applied to the study of recovery before and after surgical repair—cannot be overemphasized, as the electrical signs of recovery antedate the recovery of motion and sensation by many weeks. When a sufficient time after injury has elapsed to permit the development of a state of denervation and the characteristics of denervation are not found by electrodiagnosis, then the nerve may be said to be spontaneously recovering and should not be operated on. Likewise, if after suture of a severed nerve the characteristics of the denervated state are not found it may be assumed with certainty that recovery is taking place. On the other hand, when sufficient time has elapsed after nerve injury for regeneration to have occurred and the characteristics of denervation are found, then the nerve must be operated on.

Finally, the most important principle that affects the results of peripheral nerve surgery and is not sufficiently emphasized is that principle that stresses every effort to keep the effector mechanism in a state in which it may function. It is of little avail to have a perfect microscopic regeneration of a peripheral nerve trunk if the muscles are so atrophied and fibrosed and the joints so fibrosed and ankylosed that they will not move. Such a peripheral nerve suture may be classified as a failure and yet regeneration within the nerve trunk may be perfect. Consequently, the intensive use of physical therapy and all of its adjuncts, electrical stimulation, massage, active and passive movements, and use of proper splinting of the paralyzed extremity or portion of the extremity into a position of relaxation of the paralyzed muscle and of function of the limb is of great importance and cannot be overemphasized. Yet it is one of the factors in peripheral nerve surgery that is most often neglected.

ABSTRACT OF DISCUSSION

Dr. Loyal Davis, Chicago: In the past emphasis has been placed on the wrong factor in discussing the repair of peripheral nerve injuries. Everyone has been talking as to whether the nerve will regenerate. Nerves regenerate any time, any place, when the two ends are in apposition; as a matter of fact, it is rather difficult, experimentally, to keep a nerve from regenerating.

The important thing, therefore, is what Dr. Perret spoke about: that is the care of the effector mechanism. I consider his judgment on the matter to be sound. One cannot expect a hand, finger, or a foot to function if the muscles are atrophied, if the joints are fibrosed or ankylosed, or if the muscles are shortened because it has been allowed to stay in a malposition from the time the nerve was injured.

More attention should be paid to keeping the muscles and joints in condition by all types of physical therapy and electrotherapy so that, when the nerve does regenerate the effector mechanism can work. This explains, in many instances, the failure to accomplish good results after a nerve has been sutured.

Time is an essential factor in the results to be obtained with peripheral nerve surgery. Nerve ends should be sutured and apposed as quickly as possible after the nerve has been divided. I am in complete disagreement with anyone who deliberately delays the apposition of nerve ends.

I am quite aware of those instances in which a nerve cannot be sutured because of the destruction of the nerve, or because of other factors that involve fractures of bones in which the nerve suture must be necessarily delayed because of the circumstances.

But recently it has been stated that the way to get a good result in peripheral nerve surgery is to delay deliberately the union of the nerve. There is not a man in this room who, if when he walked out of the room happened to put his hand through the window and cut his wrist, severing his median nerve, would not want that median nerve sutured promptly.

There are many false ideas about being able to get a nerve together by flexing adjacent joints or extending them, in either case stretching the nerve. As Dr. Perret pointed out, there are great changes in the nerve microscopically, and there is a traumatic degeneration produced in a nerve by stretching that can be shown histologically. All the nerve sutures that were performed during the last war, with a leg in flexion or an arm in flexion and were then stretched out are proving, on follow-up studies, to be absolutely useless.

There arises, then, the question as to how to repair a nerve injury in which there has been large destruction of tissue. Autogenous grafts, in my opinion, are the best method of accomplishing this, but, that is often impossible. It is my opinion that cable autogenous grafts are not particularly effective.

The use of homogenous grafts is still an open question. Physicians missed the opportunity during World War II, when there were amputation centers and peripheral nerve centers in the same hospital, to prove the point whether a fresh homogenous graft would be successful in repairing a large gap in nerve tissue.

There are peripheral nerve injuries that are irreparable as far as repairing the nerve is concerned. Physicians must take advantage of all the operations that have been devised for fixing joints, for shortening tendons, and for placing the hand in the position of function so that the best possible functional results may be obtained.

Dr. Sterling Bunnell, San Francisco: Primary nerve sutures, if properly carried out, give the best results; but if performed by the usual technique, the nerves should be sutured again as soon as the limb is in condition for this. If conditions are not right for primary suture, such as in wounds with crushing and contamination, one stainless steel stitch should be placed to hold the nerve ends together, and a perfect neurorrhaphy should be performed as soon as the wounds have healed.

Similarly, if the wound becomes infected the nerve should be sutured again as soon as possible, because the degree of regeneration is in direct proportion to the accuracy of the union. The union cannot be perfect if done crudely or in the presence of infection.

The urgency of repairing nerves early, before irreversible degeneration and atrophy occur in their distal fragments and in the muscles, should be emphasized even more. Perfect nerve juncture should be accomplished as early as possible. Much muscular damage might well result if two years are allowed to elapse.

Too often attention is given to the fracture or the joint at the neglect of the nerves until too late, but arm nerves and the brachial plexus are hand nerves. Injury of them wrecks the hand, and the hand is the important part of the upper extremity. Therefore, the repair of nerves should have priority; they should be repaired at the time of setting the fracture, or before.

This is so important that, if necessary to get the nerve ends together, the arm should be bent at the fracture, or an ankylosed elbow should be broken up and flexed, so joining the nerve ends will be possible. The bones and the joints that are of lesser importance can be treated later.

Tantalum foil should never be used, and nerve homografts are not of practical value. Autogenous grafts are successful if the grafts are narrow enough to be thoroughly nourished.

This principle applies to any type of graft, nerve or otherwise. This is also why a several-strand cable graft, if properly sutured, is preferable to a single thick-nerve graft. The matter of fastening those cable grafts is a simple matter of technique; they then work beautifully.

The author mentions four ways of overcoming gaps in nerves but does not include the method of freeing the nerves liberally, flexing the joints, and transplanting the nerves so they will span the joints. This point of view was taken because of fear of stretching the nerve when the limb is again extended.

The above principle has been the chief method that I have used in repairing well over 1,000 nerves, and it is successful. A full month is allowed for the nerve juncture to become sufficiently strong.

Then, twice a week, the joints are carefully extended, a little at a time and always short of discomfort. This extension is not done rigidly by turnbuckle or by a series of casts, as this would place the nerve on a stretch. A stretch means either rupture of fibers or ischemia. Ischemia of a nerve is followed by necrosis. To avoid either of these time is given for the nerve to grow longer, not to be stretched longer.

We use the snub method; that is, the degree of each successive extension is snubbed by the splint, but the joints are always free to flex and so ease the tension. This relieves any discomfort from nerves rendered ischemic by overpull. By these methods gaps of up to five inches may be overcome in any of the three main nerves of the arm and four inches in the brachial plexus.

When arm nerves are paralyzed constant attention should be given to the hand to keep the joints supple and in position of function. Sinusoidal exercise helps. The patient should be instructed to keep the joints of the hand in good condition by moving them gently with his other hand. The paralyzed muscles should never be overstretched.

It is not necessary to splint the hand so that the paralyzed muscles are fully relaxed, as was done in World War I and in the beginning of World War II. This rigid and over-splinting will do much damage. All that is necessary is to provide some light, springy, or elastic splint that will exactly counterbalance the muscle imbalance, and no more, so the hand will remain in the position of function. The patient can then engage in occupational therapy and, by using the hand, will keep it in condition until the nerves regenerate.

Dr. Perret, Iowa City: I wish to thank Drs. Davis and Bunnell for their expert discussions. I do not have much to add, as we seem to agree fundamentally. In our experience infected wounds can be sterilized without too much trouble with adequate debridement and with the local and systemic use of today's antibiotics. Thus we have been able to successfully repair nerves in grossly infected wounds that were cleaned out thoroughly and closed tight primarily and which healed without complications.

CLINICAL NOTES

MERCURY LOST IN THE GASTROINTESTINAL TRACT

REPORT OF AN UNUSUAL CASE

Meyer O. Cantor, M.D., Detroit

Since the trend toward mercury-bearing intestinal decompression tubes developed, the innocuousness of the liquid metallic mercury in the gastrointestinal tract again has been observed.[1] A review of the literature upon the subject of bowel obstruction and the role of mercury in its treatment reveals numerous articles beginning with 1676 and appearing until approximately 1850. In these articles many case reports were found extolling the curative effect of liquid mercury in the treatment of bowel obstruction.[2] Judging from the extensive literature that accumulated on this subject during these early years, it would seem that numerous therapeutic properties were ascribed to metallic mercury in overcoming bowel obstruction. These were believed to occur by virtue of the fluidity and weight of this heavy metal, which was supposed literally to force its way through the obstructing process. This form of treatment fell into disrepute about the middle of the 19th century as a result of the observation of Dujardin-Beaumetz[3] that the mercury did not pass down the gastrointestinal tract en masse but became finely divided into small particles which could not exert any pressure effect upon the obstructive process. Despite the fact that the use of mercury fell into disrepute in the treatment of bowel obstruction, a useful objective was obtained. The extensive use of this heavy metal had called attention to its usefulness in the treatment of bowel obstruction, and this paved the way for its subsequent introduction into the end of a tube. In addition, the innocuousness of the mercury when free in the gastrointestinal tract was shown.

In the past two years case reports have appeared describing pathological processes as a result of the presence of this free mercury. Birnbaum[4] reported the development of acute appendicitis as a result of the presence of mercury globules in the appendix. Hoffman,[5] on the other hand, reported the presence within an appendix removed at operation of free metallic mercury which had produced no inflammatory change at all. Lindemuth[6] recently reported a persistent rectal fistula caused by leakage of mercury from an intestinal tube. In this case, healing of the fistula did not occur until the tract and all the mercury in its wall had been excised. It appeared that the metallic mercury acted as a foreign body preventing the spontaneous closure of the fistulous tract. Lindemuth further quoted Chodoff, who reported the escape of metallic mercury from a tube following right colectomy and illeotransversecolostomy. In this case, three intestinal fistulas developed proximal to the anastomosis. At autopsy these fistulas were shown to have adjacent abscesses, each of which contained metallic mercury.

The case report herein presented is rather unusual for two reasons: First, it presents for the first time radiological confirmation of the accuracy of the observation of Dujardin-Beaumetz, and, second, it demonstrates that persistence of fistulous tracts is not the rule as a result of a leakage of mercury.

REPORT OF CASE

A. F., a 35-year-old woman, was admitted to the North Detroit general hospital for treatment of a tubo-ovarian abscess. As a result of the surgical treatment, the colon at the rectosigmoid was opened. The rent in the colon was closed in two layers. The patient had received massive doses of penicillin, phthalylsulfathiazole, and streptomycin prior to and after operation. Despite this, pelvic peritonitis developed. This was then followed by the development of four fecal fistulous tracts in the next four weeks. One fistulous tract opened over McBurney's area; one tract opened below the umbilicus; one opened above the pubis, and one opened in the vaginal vault. During the time that the pelvic peritonitis was being treated, a mercury-bearing intestinal decompression tube was passed to treat the paralytic ileus that resulted from the intra-abdominal inflammatory process. Eight cubic centimeters of mercury had been used in the balloon. The balloon was improperly tied off. This resulted in all the mercury escaping within the gastrointestinal tract. Figure 1 shows well the escape of the free mercury within the gastro-

intestinal tract. In this figure one notices large masses of metallic mercury. Seven days later, roentgenograms showed the mercury to be finely divided into particles which beautifully outlined the entire colon as effectively as though barium sulfate had been given. Only two small masses of mercury remained intact. Figure 2 shows the fine dispersion of the mercury within

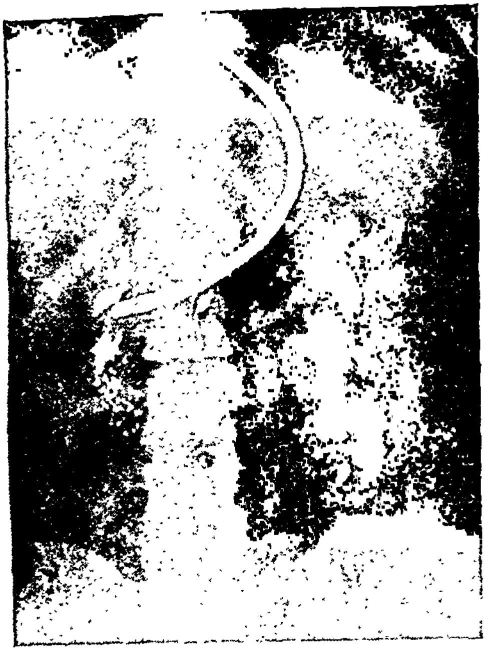

Fig. 1.—Masses of metallic mercury resulting from leakage of 8 cc. of metallic mercury from the balloon of an intestinal tube.

the colon. A barium enema showed, as seen in figure 2, that there was complete obstruction at the rectosigmoid. The fistulous tracts began just above the point of obstruction, exactly at the spot at which the dispersion particles of mercury and the barium

met. On the 20th day, in order to be certain that the fistulous tracts had their origin at the rectosigmoid, a radiopaque catheter was passed through one of the fistulous tracts, and 100 cc. of a very dilute barium suspension was injected. Figure 3 shows well that the entire right, middle, and left colon up to the rectosigmoid were visualized. Below the rectosigmoid there was no visualization because of the colonic obstruction at this point. One notices that, in figure 3, only a very small amount of metallic mercury remained. From its position, it would appear that this small amount of mercury had found its way through the vaginal fistulous tract and through the tract in McBurney's area. During the course of these four weeks globules of mercury were excreted through the fistulous tracts from time to time. On the 22d day after figure 1 was taken a defunctionizing colostomy was done to divert the fecal stream. As a result, the fistulous tracts began to close within a week. In two months all four tracts had completely closed.

SUMMARY

This case report presents radiological confirmation of the accuracy of the observation of Dujardin-Beaumetz almost 100 years ago. The mercury was so finely divided that it delineated the entire colon almost as well as barium. Four fistulous tracts developed as a result of injury to the colon. Metallic mercury was excreted through these tracts. Defunctionizing colostomy resulted in a rapid closure of these tracts. At the end of two months the closure of all four tracts was complete.

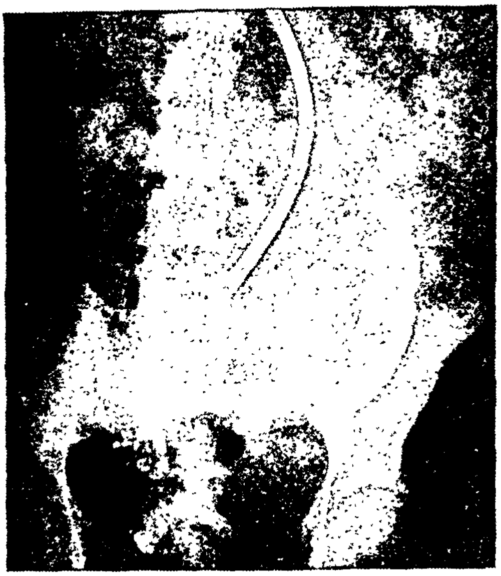

Fig. 3.—Radiopaque catheter inserted into one fistulous tract, and dilute barium injected. Note small amount of metallic mercury remaining in pelvis and in right lower quadrant. This film was taken 20 days after figure 1.

CONCLUSIONS

A roentgenological presentation of the dispersion of metallic mercury within the gastrointestinal tract is given. Such fistulous tracts do not necessarily remain persistent because of the presence of metallic mercury within the bowel. For persistence of fistulous tracts to occur, the mercury must become trapped within the tract and there act as a foreign body.

The First Great Pyramid.—Imhotep was the Grand Vizier, Chief Justice, and Physician to King Zozer, and as a side-line he was also architect of the first great Pyramid at Sakkara. He was the first great man combining the sciences of law and medicine; he might, if you wish, be described as the first medicolegal expert. Unfortunately Imhotep became a god, and it is one of the weakness of Egyptian medicine that the methods of treatment became largely empirical and irrational through the influence of tradition, heavily overlaid with an aura of divinity and magic.—Sir Sydney Smith, the History and Development of Forensic Medicine, *British Medical Journal,* March 24, 1951.

NURSING HOMES

Nursing homes have had an unprecedented growth in the past 10 years. This growth has been in response to an urgent need. Although the need probably has always existed, the demand for nursing home care was greatly increased by the Old Age Assistance Program in 1935, which made it possible to grant federal and state assistance to the aged in their own homes or in private institutions such as nursing homes. Other important factors have been the increase in the number of older persons, the shortage of general hospital beds, the general housing shortage since World War II, and the lack of other facilities for the chronically ill and for the homeless aged.

Nursing homes now provide a variety of types of care. These include substitute home or boarding home care, convalescent care, care for the aged and for the chronically ill. The services required vary from minimal help to an ambulant infirm aged person to continuous nursing care for patients bedridden because of chronic disease.

The Commission on Chronic Illness [1] reports that it is becoming more apparent that nursing homes should not remain isolated units, but should be brought into a comprehensive chronic illness program serving the community. They need the help of medical societies and other community organizations to use community services and affiliate with hospitals to bring more medical care, rehabilitation, and a fuller social life to their patients.

This can be done through such methods as the establishment of a central information service for the chronically ill in the community; contacts with community agencies and churches, and the development of a direct connection between nursing homes and hospitals, with hospitals providing guidance, consultation, and special services as needed.

The essential role of nursing homes in a well-rounded community plan for the care of the chronically ill should be recognized. Community efforts should be directed to the establishment and maintenance of good standards of care and, since most nursing homes are commercial enterprises, fee scales that will keep these facilities within the financial reach of all who need them and at the same time provide the nursing home operators with a reasonable financial return.

Licensing of nursing homes can be a positive force—and a help to all—if it is based on practical, desirable and realistic standards. There should be licensing or accrediting laws in all the states, and these laws should be administered with the objective of giving services to the operators, the patients, and the public. A powerful incentive to the passage and administration of such laws is contained in Public Law 734, 81st Congress, which amends the Social Security Act to require, beginning July 1, 1953, that, if payments of old age assistance, aid to the blind, and aid to the permanently and totally disabled are made to persons in public or private institutions, federal funds will be available only if there is a "State authority or authorities . . . responsible for establishing and maintaining standards for such institutions."

The funds to pay for reasonable costs of care in nursing homes must be made available. State and local departments of welfare must be concerned with providing sufficient funds to insure at least minimum standards of good care for the indigent chronically sick. It seems paradoxical that that portion of the sick population least able to pay for care—the chronically ill—should be left largely unprovided for by community-supported institutions and programs. Nevertheless, private nursing homes have developed in response to a need which was not otherwise being met. It is reasonable to suppose that there will always be a place for private nursing homes which offer good services at a reasonable cost. In the recently published study of the needs of terminal cancer patients made by the Chicago Central Service for the Chronically Ill,[2] it is revealed that, in those cases in which significant amounts of help must be employed for the care of the patient, the cost of care at home is greater than the cost in facilities such as nursing homes.

The function of the nursing home, and of all institutions and agencies providing services to the chronically ill, is not only to give care but to see that patients are physically or vocationally rehabilitated if possible.

Good and continuous medical supervision is essential for the chronically ill, just as for all others who are ill. When it is necessary for patients to move to and from the nursing home and the hospital or to his own home, continuity of medical supervision cannot always be assured. Although consultation and specialist services may be needed from time to time through the course of his illness, the patient should have one physician to whom he can look for guidance on continuing care. Medical societies can work with nursing homes, community agencies and hospitals to develop medical-social programs that would be aimed at preventing gaps in medical service for patients whose requirements for care result in frequent moves from hospital, to home, to nursing home—and from nursing home to nursing home.

A growing awareness of these and other problems of chronic illness is reflected in recent reports on chronic illness activities by medical societies in 20 states. Cooperation with community groups and nursing home operators could be an important field of action for the medical society chronic illness committees that have been already established, and the many new committees that will be formed as guidance and leadership by the medical profession is provided in the development of better care for the chronically ill.

AUREOMYCIN AND ANTACIDS

Aureomycin, the yellow antibiotic substance produced by the actinomycete Streptomyces aureofaciens, has had extensive clinical use since its discovery by Duggar in 1948.[1] It has a wide spectrum of chemotherapeutic activity, and its use is accompanied by a relative lack of harmful effects. Aureomycin is effective not only against many gram-positive and gram-negative bacteria, including penicillin-resistant and streptomycin-resistant strains, but also against Rickettsia and certain viruses. Furthermore, organisms show little tendency to develop resistance to aureomycin.

Intramuscular injection of aureomycin results in local irritation, unpredictable blood levels and unsatisfactory therapeutic results.[2] Oral administration results in satisfactory therapeutic results but is accompanied by high incidence of gastrointestinal upsets, including loss of appetite, nausea, vomiting and epigastric pain. Effects directed toward reduction of these gastrointestinal upsets include the use of more purified preparations and administration with adjuncts such as gastric antacids and milk. The effectiveness of an aluminum hydroxide gel preparation in relieving aureomycin-induced nausea was first reported by Schoenbach, Bryer and Long [3] in 1948, but at this time techniques were not available for studying the effect of this antacid on the aureomycin blood level. The following year, Di Gangi and Rogers, using both colorimetric and bacteriologic assay methods, showed that aureomycin in vitro was adsorbed onto aluminum hydroxide gel.[4] At the same time, Waisbren and Hueckel [5] studied the effect of aluminum hydroxide gel on the aureomycin blood levels of six normal male subjects and five hospitalized patients receiving 500 mg. of aureomycin every six hours. When approximately 30 cc. of aluminum hydroxide gel was administered immediately after each dose of aureomycin, the blood levels of aureomycin in 10 of the subjects fell from an average of about 5 micrograms per milliliter to less than 1 microgram per milliliter. One of the 10 patients suffered a recurrence of a urinary tract infection with the combined treatment, which promptly subsided when administration of aluminum hydroxide was discontinued. Confirmatory evidence that aluminum hydroxide gel may interfere with the absorption of aureomycin from the gastrointestinal tract is provided by the reports of Seed and Wilson [6]; Boger, Matteucci, Beatty and Baganz [7]; Bartholomew and Nichols [8]; Michel, Sayer and Kirby [9]; Greenspan, MacLean, Milzer and Necheles,[10] and Williams and Weekes.[11] On the other hand, Bartholomew and Nichols showed that the administration of milk with aureomycin reduced the incidence of gastrointestinal irritation and vomiting without lowering aureomycin plasma levels. In addition, Greenspan and his co-workers showed that the polycarboxylic acid antacid, sodium carboxymethyl cellulose, did not adsorb aureomycin in vitro or interfere with absorption of the antibiotic from the intestine, while the report of Williams and Weekes indicates that mucin-aluminum hydroxide-magnesium trisilicate reduces the nausea and vomiting incident to aureomycin administration without lowering the blood level of the drug.

It would thus appear that antacid therapy and systemic aureomycin therapy may be undertaken simultaneously, provided it is known that the antacid used does not affect the serum levels of the aureomycin. For gastrointestinal infections, administration with an adsorbing antacid might result in higher or more prolonged local concentrations of the drug. In many instances, however, the use of milk appears to be a simple, cheap and effective method of reducing the incidence of gastrointestinal upsets accompanying aureomycin therapy without interfering with the absorption of the drug from the gastrointestinal tract.

POSTGRADUATE CONTINUATION COURSES FOR PHYSICIANS

The semiannual listing of postgraduate continuation courses for physicians, covering the period July 1 to Jan. 15, 1952, appears elsewhere in this issue. These data prepared as a regular service by the Council on Medical Education and Hospitals list 873 courses varying in length from a few days to several months. Some are concentrated full time courses and others are part time. There are opportunities for the physician in general practice as well as the specialist. In addition, a series of courses for military personnel at medical installations are included. Courses are being given in 32 states and in the District of Columbia. The subjects embrace 46 major areas in the field of clinical medicine and the basic sciences. Noteworthy among the courses listed are the opportunities offered for the physician in general practice. Medical schools, state medical societies, hospitals, state and city boards of health, and special societies continue to be active in developing this type of continuation training.

One hundred and seven agencies are participating in sponsoring the courses in this listing, including 37 medical schools, 17 special medical societies, 13 hospitals, 12 graduate schools of medicine and graduate assemblies, 7 state chapters of the American Academy of General

Practice, 6 schools of public health, 5 state medical societies, 4 county medical societies, 4 government agencies, and 2 health departments.

Institutions offering this type of training are invited to announce such courses in the Council's semiannual listing.

EXAMINATION AND CERTIFICATION OF PROSTITUTES

On two occasions the American Medical Association has declared its position with regard to the medical examination and certification of prostitutes. In 1942 the Association's House of Delegates passed and in 1945 the House reaffirmed the following statement:

> First, that the control of venereal disease requires elimination of commercialized prostitution; second, that medical inspection of prostitutes is untrustworthy, inefficient, gives a false sense of security and fails to prevent the spread of infection; third, that commercialized prostitution is unlawful, and physicians who knowingly examine prostitutes for the purpose of providing them with medical certificates to be used in soliciting are participating in an illegal activity and are violating the principles of accepted professional ethics.[1]

The American Social Hygiene Association, as a result of field studies made during the past two years, has reported to the American Medical Association that, while great progress has been made, there is a small number of physicians in the few cities still tolerating commercialized prostitution who continue periodically to examine prostitutes and provide them with certificates for use in soliciting trade. With military and industrial mobilization for national defense now in progress, it may be desirable to review the reasons that led the American Medical Association to declare such practices unethical.

Prostitution itself and aiding or abetting prostitution are unlawful in all but one state. The physician who examines prostitutes and gives them certificates implying freedom from venereal diseases is a collaborator in an unlawful racket. He aids a business which degrades morals, causes corruption and spreads dangerous infections and which is carried on for profit distributed 20 per cent to the prostitute and 80 per cent to her exploiters. The doctors' fees come out of the 80 per cent assigned to the exploiters.

The fact that the prostitution racket can, in a few places, be carried on apparently under the respectable mantle of medical supervision makes the task of law-enforcement officials more difficult, because physicians appear to be taking responsibility for preventing the spread of venereal diseases by the prostitutes whom they inspect. The general public in such communities is influenced by the example of the physician who examines and certifies the women and girls engaged in prostitution. Citizens assume that, if a doctor examines the "girls on the line," he must consider it right to have a "line" and that, being a doctor, he knows about such things. Local citizens, therefore, may not support or insist on the enforcement of the laws against prostitution.

Prostitutes and their agents want "health cards" for their value in attracting trade. They know ignorant prospective customers will believe that, because a doctor examined a woman and certified her as "blood test negative, smear negative," they may have sexual relations without risk of infection. A familiar sales talk of the pimps and madams is: "Our girls are all clean. Our doctor examines each one every two weeks. You'll find the doctor's certificates right in the girls' rooms." A feeling of security absolutely unwarranted by medical facts is given by the doctor's certificate. Between examinations a prostitute must have an average of 10 sexual contacts per day in order to pay expenses. Even if really free from any infectious disease at the time of the doctor's examination, a prostitute may become a carrier of disease with her first postexamination contact or any subsequent contact. Even if she were examined daily, no reliable assurance could be given that a prostitute would not spread venereal diseases.

Before a conscientious physician could express a valid opinion regarding the presence or absence of one or more venereal diseases in a woman who by occupation is many times daily exposed to the probability of infection, he would be required to make, at least daily, careful clinical examination including inspection of all skin and accessible mucous membrane surfaces. He must in all cases take blood for serologic tests for syphilis and specimens from at least four sites for spreads and cultures for the gonococcus. Any lesion of the skin or mucous membrane, especially of the genital, anal and oral regions, must be regarded with great suspicion and carefully examined. This would require biopsies and spreads for Donovan bodies of granuloma inguinale and spreads for Ducrey's bacillus. Most important, every suspicious lesion must be examined, repeatedly if necessary, by the dark field method for Treponema pallidum. Skin tests for lymphogranuloma venereum and chancroid may be indicated. The initial examination would require 30 to 60 minutes of the doctor's time. The total cost would be \$35 to \$50 for private medical and laboratory services. If any suspicious lesions were found, it might be a week or more before the physician could offer a valid scientific opinion regarding the presence or absence of venereal diseases. If no lesions were discovered, the physician should still suspect that he had overlooked one too small to be seen easily.

Obviously no such thorough examinations and, if necessary, follow-up observation of prostitutes are or can be made anywhere in the United States or abroad, but any less careful study is unworthy of the medical profession, even if there were no other compelling reasons for refusing to be a party to the prostitution racket.

The policy of the federal government, stated in the "Eight Point Agreement" signed by representatives of the Department of Defense and the Federal Security Agency, calls for the repression of prostitution, especially where the health and welfare of the nation's fighting men—many of them minors—are involved. No less important is the protection of the youth of the nation outside the armed forces. Patriotic motives, as well as a decent respect for medical ethics and law, should lead those few physicians who have been cooperating with prostitution rackets immediately to cease examining and certifying the unfortunate women who are exploited in a vicious and cruelly selfish traffic.

ORGANIZATION SECTION

DR. LEVIN RETURNS TO NEW YORK

Dr. Morton L. Levin, who has directed the program of the Commission on Chronic Illness on a leave of absence from the New York State Department of Health, has been recalled to his position as assistant commissioner for medical services and will return to Albany early this summer, it was announced by Mr. Leonard W. Mayo, chairman of the commission. During the year of Dr. Levin's directorship, the commission's education-research program has made rapid strides. Two studies of prevalence of chronic illness were initiated, one in a rural area and another among city dwellers. The rural study is now being launched in New Jersey by the Hunterdon (N. J.) Medical Center. The study will be carried out by Dr. Ray Trussell, medical center director, with a $60,000 grant from the Commonwealth Fund and plans developed by the commission.

The Commission on Chronic Illness is composed of 33 persons, professional and lay, interested in the problem of chronic illness. It was founded in May, 1949, as the result of the coordinated efforts of four national organizations, the American Hospital Association, the American Medical Association, American Public Health Association, and the American Public Welfare Association.

CIVIL DEFENSE PICTURE ADDED TO A. M. A. LIBRARY

The American Medical Association is one of the first organizations to receive prints of "Survival Under Atomic Attack," the first of a series of official Civil Defense Administration motion pictures. It deals with action the individual can take to protect himself in the event of attacks that may come either with or without warning. The film is black and white, sound, 16 mm., and runs nine minutes. It is available from the Committee on Medical Motion Pictures at a service charge of $1.00 plus transportation.

MEDICAL LEGISLATION

FEDERAL

Child Life Research

A bill to provide for research in child life, H. R. 4094, was introduced by Representative Elliott of Alabama. It would authorize 7½ million dollars annually to enable the federal security administrator to conduct and foster research in child life. Funds could be expended in grants-in-aid to schools and other public or nonprofit agencies. The bill is identical with S. 676, previously reported in The Journal.

Physically Handicapped Children's Education

Representative Kelley of Pennsylvania introduced H. R. 4136, which would enable the states to make more adequate provision for special services required for the education of physically handicapped children of school age. The bill proposes an appropriation of 4 million dollars for fiscal year 1952, gradually increasing the annual appropriations to 16 million dollars by 1955. This bill is identical with a previously reported bill, S. 1463.

Maternity Benefits for Wives of Servicemen

H. R. 4176, introduced by Representative Mitchell of Washington, proposes to establish a program of grants-in-aid to assist the states to provide maternity and infant care for the wives and infants of enlisted members of the armed forces during the present emergency. This bill would set up an Emergency Maternal and Infant Care program similar to the one in effect during World War II. An identical proposal was introduced earlier in the Senate as S. 1245, which has been previously reported.

STATE

Alabama

Bills Introduced.—H. 215, proposes that every person engaged in any business, vocation, occupation, calling, or profession enumerated in the bill shall pay a license fee in amounts specified. The bill enumerates physicians and other professions and the license fee varies from $15 to $100, depending upon the gross annual receipts of the individual's practice. S. 147, proposes regulations for the sterilization of mentally inferior or mentally deficient or feeble minded inmates in the Partlow State School for Mental Deficients.

Delaware

Bill Enacted.—H. 443, was approved May 14, 1951. It empowers the Medical Council of Delaware, by general regulation or specific orders, to issue temporary emergency certificates, said temporary certificates to be limited to twelve months duration, renewable at the discretion of the issuing authority, to such physicians and dentists licensed in another state as they shall find qualified to practice as such in the state during an emergency. The holder of this temporary certificate shall be privileged during the term specified therein to practice his profession in the state subject to such regulations, restrictions, and area limitations as the Medical Council may impose.

Florida

Bills Introduced.—H. 302, proposes the enactment of a new law regulating the practice of registered and practical nursing. H. 383, to amend the law relating to dealing in dead bodies, proposes that nothing in such law should be construed to prohibit the obtaining, dissecting, using and disposing of dead bodies for the purpose of teaching or other appropriate university research by any medical school, dental school, school of nursing or other university research or teaching unit which is a part of a regularly established or chartered institution of higher learning in the state. H. 1047, proposes that all citizens and tax payers of Bay County, Florida, shall have the right to be admitted to any hospital supported in whole or part by taxes and in the management of such hospital no discrimination shall be made against any physician or surgeon, provided such physician or surgeon has been admitted to the general practice of medicine or surgery under the laws of the state and all such physicians or surgeons shall have equal privileges in treating patients in such hospitals. H. 1059, proposes to authorize the state board of education to grant licenses to psychologists. A person practices psychology, under this proposal, when he renders to individuals or to the public any service involving the professional application of recognized principles, methods and procedures of the science and profession of psychology or when he holds himself out as being able to, or undertakes by whatever means to evaluate, appraise or classify mental abilities, personality characteristics, or personal or interpersonal maladjustments, or to perform psychological reeducation, psychological readjustment, psychological guidance, or counseling. Nothing in the proposal would permit a licensee to perform any physical or medical examination or to administer any physical or medical treatment. S. 712, proposes to direct the Board of Commissioners of State Institutions to select an advisory committee to study and survey possible State Hospital sites in the Tampa-Bay area and the lower east coast for the purpose of recommending a specific site for the construction of two branches of the Florida State Hospital. S. 775, proposes the creation of a Florida state board of electrolysis examiners and defines electrolysis as the method of removing superfluous hair from the human body by means of the application of an electrical current to the hair papilla, warts and benign growths by means of a needle or needles to cause decomposition of the hair-papilla and thus permanently remove the hair. S. 797, proposes to acquire practitioners of medicine, surgery, osteopathy, chiropractic, naturopathy, etc., to place a sign in a conspicuous place at the entrance to his office indicating the particular kind or branch of the medical or material healing art which he is licensed to practice. The proposal would further require that every sign showing the word "Doctor," "Dr." or "Physician" or any abbreviation thereof, shall indicate the person's name and the branch of healing arts which such person represents. S. 798, relating to naturopathy, proposes to require annual registration of naturopaths and further proposes to define naturopathy as the use and practice of psychological, mechanical and material health sciences to aid in purifying, cleansing and normalizing human tissues for the preservation or restoration of health, according to the fundamental principles of anatomy, physiology and applied psychology. Naturopathic practice shall employ and embrace the use of light, air, water, clay,

---

The summary of federal legislation was prepared by the Washington Office of the American Medical Association and the summary of state legislation by the Bureau of Legal Medicine and Legislation.

heat, rest, diet, external applications, mechanical and electrical appliances, suggesto-therapy, hydrotherapy, zone therapy, hygiene, first aid and sanitation; provided, however, that nothing in the proposal would be held or construed to authorize any naturopath to practice materia medica, surgery, or chiropractics or to prescribe or administer hypnotic or narcotic drugs.

Bill Enacted.—H. 95 became Law Without Approval May 9, 1951. It authorizes the **state board of medical examiners** to appoint or employ an assistant secretary or secretaries who need not be licensed physicians and to fix the salary of such assistants.

Illinois

Bills Introduced.—H. 950, to amend the law relating to chiropody, proposes to authorize the use of the **injunctive process** to enforce the provisions of the Chiropody Act. H. 953, to amend the law relating to pharmacy, proposes to authorize the use of the **injunctive process** to enforce the provisions of the Pharmacy Act. H. 954, to amend the law relating to nursing, proposes to authorize the use of the **injunctive process** to enforce the provisions of the Public Health Nursing Act. H. 959, to amend the law relating to the practice of medicine, proposes to authorize the use of the **injunctive process** to enforce the provisions of the Medical Practice Act. S. 598, to amend the law relating to a Medical Practice Act, proposes that one member of the **Medical Examining Committee** shall be an osteopath and one shall be a chiropractor and that in appointing such members due consideration shall be given to the recommendations of representative, osteopathic and chiropractic organizations.

Bills Enacted.—H. R. 45 was adopted March 28, 1951. It resolves that the **Hadacol Company** be notified that it is neither in the best interest of the people of the State of Illinois nor to the advantage of the manufacturer of Hadacol to use testimonials of young children to advertise a product of such a nature. S. R. 53, was adopted May 10, 1951. It provides for the appointment of a special committee to study the need for the establishment of a hospital in Chicago for the treament of **acute mental patients**, especially those addicted to the habitual use of narcotics and alcohol. S. R. 60, was approved May 16, 1951. It resolves the creation of a special committee to investigate the reasons why the City of Chicago, despite its need for additional beds for the treatment of **tuberculosis**, has not and does not use the facilities of the Municipal Contagious Disease Hospital for the treatment of such citizens.

Maine

Bill Enacted.—S. 243, was approved April 27, 1951. It amends the law relating to the Board of Registration in Medicine by authorizing such board to issue **reciprocity certificates** under certain circumstances.

Maryland

Bill Enacted.—H. 512 has become Chapter 701 of the Laws of 1951. It requires the **annual registration** of chiropractors.

Michigan

Bill Introduced.—H. C. R. 65, proposes the creation of a special committee to study the laws of the state governing **drug addicts** and to report their findings and recommendations.

Minnesota

Bills Enacted.—H. 113 has become Chapter 672 of the Laws of 1951. It provides for the creation of a **state board of examiners of psychologists.** H. 1585 has become Chapter 479 of the Laws of 1951. It authorizes the State Board of Medical Examiners to license and regulate the practice of **physical therapy**, which is defined to mean the treatment of any bodily or mental disorder of any person by the use of the physical, chemical, and other properties of heat or cold, light, water, electricity, massage, mechanical devices, and therapeutic exercise, which includes posture and rehabilitation procedures, provided, however, the use of roentgen rays and radium for diagnostic and therapeutic purposes, and the use of electricity for surgical purposes, including cauterization, shall not be authorized under the term "physical therapy."

Missouri

Bills Introduced.—H. 486, proposes the establishment as soon as possible of a full and complete **four year course of medical and surgical instruction** in the state under the direction and control of the Board of Curators of the University of Missouri. H. 490, proposes the creation and establishment under the direction of the division of mental diseases of a state hospital for the care, treatment and rehabilitation of **chronic alcoholics.** S. 214, proposes the creation of a state board of examiners in psychology to grant certificates to **certified psychologists** and **certified psychotechnicians.**

New Hampshire

Bill Enacted.—S. 16 has become Chapter 27 of the Laws of 1951. It amends the medical practice act by, among other things, authorizing the Board of Medical Examiners to issue **temporary five year licenses** to alien physicians who had taken out their first citizenship papers and are otherwise qualified for a license. If the alien becomes a citizen during the five years, he shall be issued a permanent license.

New Jersey

Bill Enacted.—A. 1, has become Chapter 69 of the Laws of 1951. It provides regulations for the establishment of **consolidated local health districts and county local health districts.**

Ohio

Bill Introduced.—S. 266, proposes the creation of a **state naturopathic board of examiners** and defines naturopathy as a system of drugless treatment of disease by methods that simulate or assist nature, including phytotherapy, dietetics, physical, mechanical, hygenic, and sanitary methods, essential to the preservation of health.

Oklahoma

Bill Enacted.—H. 241, was approved April 25, 1951. It provides regulations for the licensing of institutions desiring to obtain **animals from established dog pounds** for the purpose of investigation or instruction concerning the structure or functions of living organisms, the causes, preventions, control, or cure of diseases or abnormal conditions in human beings or animals.

Pennsylvania

Bills Introduced.—H. 1084, proposes regulations for making available to licensed institutions **unclaimed and unredeemed dogs** and cats in public pounds for scientific investigation experiment or instruction. H. 1102, proposes to grant to **hospitals a lien** on rights of action and counterclaims that any person admitted to such hospitals for care and treatment of personal injuries shall have against any other person on account of such injuries. The extent of such lien would be the amount of the reasonable charges of the hospital for the care and treatment of such person. H. 1137, proposes an appropriation for the general maintenance and operation of the Western State **Psychiatric Institute** and Clinic by the University of Pittsburgh. H. 1139, to amend the law relating to osteopathy, proposes to increase the **annual registration fee** from three to five dollars. H. 1192, proposes to amend the **definition of chiropody** so that such practice would not include the amputation of the leg, foot, or toes or the treatment of systemic diseases of the bones, ligaments, or muscles of the feet or any part of the body. H. 1205, proposes to authorize the State Department of Health to issue licenses to persons desiring to operate a **clinopathologic laboratory** which is defined as a place, establishment or institution operated by one or more individuals for the study of blood, urine, feces, and other secretions and excretions and parts of the human body such as tumors removed for examinations in connection with the study of possible diseases in the living patient. S. 559, proposes an appropriation to the Department of Health for the operation, maintenance and purchase of equipment of the Institute of **Cancer Research** Incorporated. S. 635, proposes that in any prosecution for a violation of the law relating to **driving a vehicle while under the influence of intoxicating liquor** the amount of alcohol in the defendant's blood at the time alleged as shown by chemical analysis of the defendant's blood urine, breath or other bodily substance shall give rise to certain presumptions as to whether or not the person is guilty of the charge. The proposal would also provide that operating a motor vehicle while under the influence of any narcotic or habit producing drug shall be a crime .

Bill Enacted.—H. 719 was approved May 10, 1951. It provides a deficiency appropriation to assist State-aided medical and surgical hospitals in meeting the cost of **training student nurses.**

Rhode Island

Bills Enacted.—H. 748, was approved May 3, 1951. It provides for the creation of a special committee to make a study of the feasibility of setting up a **medical school at Rhode Island State College.** H. 752, was approved May 1, 1951. It provides for the creation of a **division of alcoholism** to promote or conduct educational and preventive programs relating to alcoholism.

Texas

Bills Introduced.—H. C. R. 108, would resolve that the House go on record as requesting this Board of State Hospitals and Special Schools to take the necessary steps to meet the **minimum standards required** in order to qualify the said hospitals and special schools operated by the State of Texas to the necessary standards for residency, intern and nurses training programs so that the patients of the said hospitals and special schools be given the highest type of medical care and treatment possible. H. 798, proposes regulations which would authorize adjoining cities, towns and villages to jointly establish, erect and equip **hospitals.**

Bill Enacted.—H. 111, was approved May 10, 1951. It provides, among other things, that all practitioners of the healing art shall indicate on any sign, pamphlet, letterhead or the like, a **designation of the system of the healing art** which such individual is licensed to practice.

Wisconsin

Bill Introduced.—S. 795, relating to the disposition of **dead bodies**, provides that if a corpse is found in the Mendota state hospital district then the University of Wisconsin shall be notified that it may have such corpse; if the corpse is in the Winnebago state hospital district, that Marquette university or any accredited school of mortuary science at Milwaukee shall be notified that it may have such corpse.

Bill Enacted.—A. J. R. 74 was adopted May 4, 1951. It directs the education committee of the legislative council to make a survey of **sanitation and safety in the public schools.**

MEDICAL NEWS

COLORADO

Summer Clinics at Children's Hospital.—The annual summer clinics of Children's Hospital, Denver, will be held June 20-22. The guest speakers are Dr. Alexis F. Hartmann, pediatrician, St. Louis; Dr. Herbert E. Coe, pediatric surgeon, Seattle, and Dr. Douglas N. Buchanan, pediatric neurologist, Chicago. Each guest speaker will conduct a two-hour clinic on one of the three days, give a lecture on a subject of general interest within his field, and appear with staff members and guests in panel discussions of pertinent subject matter of common interest and concern to all physicians interested in the care of infants and children. In addition, the guest speakers and staff members will take part in a question-and-answer period after luncheon on each of the three days. Further information concerning the clinics may be had, and registration for the clinics may be accomplished, by calling or writing to the chairman at the hospital.

CONNECTICUT

Outbreak of Trichinosis.—Dr. James C. Hart of Hartford, a member of the state department of health, has reported to the U. S. Public Health Service a family-group outbreak of trichinosis in Bridgeport. Homemade Italian sausage prepared with ham purchased from a large packing house was eaten by the family on April 4. Symptoms appeared 12 days later in the father, mother, two daughters, and a daughter-in-law. Nausea, diarrhea, vomiting, and swelling of the eyelids preceded the onset of muscular pains in each case.

GEORGIA

State Medical Election.—The Medical Association of Georgia at its annual session in Augusta in April installed Dr. William F. Reavis of Waycross as president. Other officers include: Dr. Cornelius F. Holton, Savannah, president-elect; Dr. David H. Poer, Atlanta, secretary-treasurer, and Dr. Charles H. Richardson Sr., Macon, delegate to the American Medical Association.

ILLINOIS

New Cancer Clinic.—The 26th cancer diagnostic clinic established by the state department of public health has been opened at Fairfield Memorial Hospital in Fairfield. The meeting of the clinic will be held beginning at 1 p. m. on the third Monday of each month. Persons may be admitted to this clinic for cancer diagnostic service on referral by their physician or dentist.

Psychiatric Residency Training.—The Illinois Department of Public Welfare has outlined a program that will offer residents in psychiatry three years of training in approved mental hospitals affiliated with the department. These residents will be able to fulfill the requirements of the training programs suggested by the American Board of Psychiatry and Neurology. One and one-half years will be spent in state mental hospitals, and another one and one-half years will be devoted to the various specialties. The program will go into effect July 1. Residents in psychiatry will be assigned to individual hospitals. A representative of the chief medical officer will act as liaison officer between the department of public welfare and the various institutions. The educational residency training committee will serve as advisory counsel for the chief medical officer and the residents for complaints or suggestions.

Chicago

Award Ricketts Medal.—Herald R. Cox, Sc.D., director of viral and rickettsial research for the Lederle Laboratories Division, American Cyanamid Company, Pearl River, N. Y., received the Howard T. Ricketts gold medal May 7. The medal, established in 1949 in memory of Dr. Ricketts, a University of Chicago physician, is awarded for outstanding achievement in medicine. Dr. Cox was cited for having discovered Q fever in the United States.

Joseph A. Capps Prize.—The Institute of Medicine of Chicago offers this biennial prize of $600 for the most meritorious investigation in medicine or in the specialties of medicine. The investigation may be also in the fundamental sciences, provided the work has a definite bearing on a medical problem. Competition for 1951 is open to graduates of Chicago medical schools who completed their internship or one year of laboratory work in 1949 or thereafter. Manuscripts must be submitted to the Secretary of the Institute of Medicine of Chicago, 86 E. Randolph St., not later than Dec. 31. The manuscript of the prize paper is to become the property of the Institute of Medicine of Chicago. If no paper presented is deemed worthy of the prize, the award may be withheld at the discretion of the board of governors.

IOWA

A Family of Doctors.—The fact that a doctor's sons often follow in their father's footsteps is illustrated by the Gilfillan family, in which the sixth generation is carrying on the family tradition. Dr. Homer J. Gilfillan of Bloomfield, who retired recently after 50 years in country practice in Iowa, had six sons who graduated from the University of Iowa School of Medicine. Until the recent death of the eldest, Dr. George William Gilfillan, all sons were in active practice. Ever since Dr. Alexander V. Gilfillan began practice in Philadelphia in 1796 this family has been active in the medical profession. According to *The Centaur*, Alpha Kappa Kappa's official journal, some member of this family has served in every war in which this country has engaged since the War of 1812. Five of the Gilfillan brothers saw active duty in World War II, and on return from service four entered practice in Bloomfield; the other two brothers are in practice in San Francisco and Sault Ste. Marie, Mich., respectively. A grandson is now taking premedical work at Iowa Wesleyan College.

MASSACHUSETTS

Society Election.—At the yearly meeting of the Massachusetts Society of Examining Physicians, held at the Harvard Club in Boston May 2 the following persons took office for the ensuing year: Dr. John J. Crowley, Lynn, president; Dr. John Leo Doherty, Boston, president-elect; Dr. Robert C. Gwin, Brookline, treasurer, and Dr. J. Robertson Knowles, Boston, secretary.

Cancer Research Institute and Joslin Auditorium.—Dedication exercises for the New England Deaconess Hospital Cancer Research Institute and the Elliott P. Joslin Auditorium were held June 5 in Boston. An address by Sumner T. Pike, vice chairman of the U. S. Atomic Energy Commission, Washington, D. C., was followed by an inspection of the new facilities. At the scientific session Dr. Sidney Farber, Boston, delivered the principal address. The scientific aims of the Cancer Research Institute were discussed by Dr. Shields Warren, Boston. Dr. Charles H. Best, Toronto, Canada, spoke in the evening at the dedication of the Joslin Auditorium. His subject was, "Medical Research and World Health." The institute combines under one roof cancer research, atomic research, cancer control and cancer diagnosis, outpatient department tumor clinics, and postgraduate medical instruction in cancer. The research activities will include biological chemistry, biophysics, biostatistics, clinical contacts, experimental pathology, hematology, radiobiology, and x-ray diffraction. The Institute will house also the cancer control unit of the Harvard School of Public Health, the Massachusetts State Tumor Diagnosis Service, the pathology laboratory of the Harvard Cancer Commission, and an auditorium for the use of the staffs of the New England Deaconess Hospital and Cancer Research Institute.

Physicians are invited to send to this department items of news of general interest, for example, those relating to society activities, new hospitals, education and public health. Programs should be received at least three weeks before the date of meeting.

MINNESOTA

Outbreak of Salmonellosis.—Dr. Dean S. Fleming of Minneapolis, a member of the Minnesota Department of Health, has reported to the U. S. Public Health Service an outbreak of Salmonella typhimurium infection, the suspected source of which was raw turkey eggs used in preparing the eggnog from which the organism was isolated. Ten of the 11 persons who drank the eggnog became ill with gastro-enteritis seven to 24 hours later. Salmonellosis typhimurium was isolated from nine of the 11 persons, including one who did not have clinical symptoms.

Personals.—Dr. S. Marx White, Minneapolis, received the annual distinguished service award of the Community Chest and Council of Hennepin County in January. Dr. White, who has practiced in Minneapolis for more than 50 years, has been president of the state board of health and the Community Chest and member of the county sanatorium commission.——Dr. John F. Pohl of Minneapolis left early in April on a three month fellowship in Europe under the World Health Organization to study treatment, care, management and employment of crippled children and adults in England, Germany, France and Austria.

NEW YORK

Postgraduate Lecture.—The Herkimer County Medical Society meeting at the Pinecrest Sanatorium, Salisbury Center, June 12 will hear Dr. Milton Plotz, Brooklyn, speak on "Hypertension and Coronary Heart Disease." The program has been arranged by the Medical Society of the State of New York in cooperation with the New York State Department of Health.

Course on Electron Microscope.—The summer laboratory course in techniques and applications of the electron microscope will be given again this summer by the laboratory of electron microscopy in the department of engineering physics at Cornell University July 9-21. Inquiries should be addressed to Prof. Benjamin M. Siegel, Department of Engineering Physics, Rockefeller Hall, Cornell University, Ithaca, N. Y.

Fellowships in Arthritis.—The Arthritis and Rheumatism Foundation is offering research fellowships in the basic sciences related to arthritis. Fellowships will be granted at both the predoctoral and the postdoctoral levels. The predoctoral fellowships will range between $1,500 and $3,000 per annum, and the postdoctoral from $3,000 to $6,000. Application forms may be obtained from the Medical Director, Arthritis and Rheumatism Foundation, 535 Fifth Ave., New York 17, before Nov. 15.

New York City

The Sixth Premature Infant Center.—Dedication ceremonies for the new Premature Infant Center at Bellevue Hospital were held May 22. The center, with a capacity of 32 infants and constructed at a cost of $48,000, is one of six such centers in operation or being constructed and equipped in the municipal hospitals, with one-third of the cost met with federal funds under the Hill-Burton Bill. The other centers are in Harlem, Queens General, Kings County, Fordham, and Lincoln hospitals. City-wide figures on the incidence of prematurity show that 8.5% of all live births are premature by weight definition. Fourteen per cent of these prematurely born infants die during their first year.

Clinic for Therapeutic Radiology.—Ground was broken May 18 for the new $160,000 underground Henry Harrington Janeway Clinic for Therapeutic Radiology at Roosevelt Hospital. The money has been raised from individual contributions, gifts from foundations, and a benefit sponsored by the hospital volunteers. The radium, valued at one million dollars, has been loaned to the hospital for five years by the Union Miniere du Haut Katanga of Belgium through the Radium Chemical Company, the American representative. The department was named for the late Dr. Henry Harrington Janeway, a pioneer in radium work who was later director of the early radium projects at Memorial Hospital. Dr. Douglas Quick will be director of the Janeway Clinic. The department will be located underground between the Russell Memorial Building and the Tower Memorial Building. The radium is being processed in Brussels and is expected to arrive simultaneously with the completion of the department in September.

VIRGINIA

University Appointments.—Dr. Lester A. Wilson Jr., instructor in obstetrics and gynecology, Duke University, Durham, N. C., was appointed assistant professor of obstetrics and gynecology at the University of Virginia Department of Medicine, Charlottesville, effective May 1. Edwin W. Pullen, instructor in biology at the university, has been appointed instructor in anatomy effective Sept. 1.

Death of Executive Secretary-Treasurer.—Mr. Henry S. Johnson, executive secretary-treasurer and public relations director of the Medical Society of Virginia, died May 23 after a short illness. Mr. Johnson was a graduate of the University of Richmond, held an M. A. degree from the University of Virginia, and did graduate work at the College of William and Mary and New York University. He formerly represented Goochland County in the state house of delegates and had many friends in the House of Delegates of the American Medical Association.

WEST VIRGINIA

Personal.—Dr. James L. Thompson of Weirton has been named chief surgeon and director of the medical department of the Weirton Steel Company at Weirton, succeeding Dr. Lewis A. Whitaker, who has retired after 23 years of service with the company but will continue as a consultant to the medical department. Dr. Thompson has been Dr. Whitaker's assistant for the past 16 years.

County Society Postgraduate Program.—The second annual postgraduate session of the Barbour-Randolph-Tucker Medical Society will be held at the Tygart Valley Country Club near Elkins June 21 with Dr. Charles L. Leonard of Elkins serving as moderator. The following scientific program will be presented, beginning at 2 o'clock:

Samuel P. Martin, Durham, N. C., Treatment of Common Respiratory Disorders.
Bill L. Martz, Indianapolis, Anion Exchange, Resins: A New Concept in the Treatment of Edema.
Brian Blades, Washington, D. C., Bronchiogenic Carcinoma.

Dr. Delivan A. MacGregor, Wheeling, will be toastmaster at the annual banquet in the evening, and the guest speaker will be Lt. Col. Colin F. Vorder Bruegge (MC) USA, Institute of Pathology, Washington, D. C. A general invitation has been extended to members of the West Virginia State Medical Association to attend the meeting.

WISCONSIN

Marquette Alumni Meeting.—The Marquette Medical Alumni Association will hold a luncheon meeting at the Hotel Dennis in Atlantic City, N. J., on Tuesday, June 12. Father Clarence J. Ryan, regent of the alumni association, and Dr. John S. Hirschboeck, dean of Marquette University School of Medicine, Milwaukee, will speak. Marquette medical alumni should make reservations with the Alumni Association office, 1533 W. Wisconsin Ave., Milwaukee.

Diabetes Control Program.—This program in Milwaukee, which was staffed by the personnel of the U. S. Public Health Service, closed in February after 22 months in which it gave free diabetes detection tests to study the effectiveness of various diabetes detection programs. The Public Health Service funds have been diverted into the field of civil defense. The testing began in the fall of 1949 in the first of three Milwaukee areas of 10,000 population each. Three plans of educational approach were used: door-to-door distribution of literature, supplemented by house-to-house visits by city health nurses, and the community approach to lay groups. Blood-sugar tests were used for most of the people in the three areas, rechecks of non-negative tests were made and follow-up was completed. Physicians reported to the program on the final diagnosis. In the blood-sugar testing program nearly 5,000 persons were examined. About

250 were referred to their private physicians, and 180 were previously undetected diabetics who were placed under treatment by the physician of their choice. On Oct. 16 the program changed from blood-sugar testing to urine testing and was conducted in industrial plants. Of 6,300 containers returned, 26 patients were diagnosed as previously undetected diabetics and were put under the care of their family physicians. Final accurate statistical evaluation of the data will not be available until tabulated by the U. S. Public Health Service.

GENERAL

American Diabetes Association.—The 11th annual meeting of the American Diabetes Association will be held at Chalfonte-Haddon Hall, Atlantic City, N. J., June 9-10 under the presidency of Dr. Lester J. Palmer, Seattle. In addition to the scientific program there will be a conference of presidents of affiliate associations Saturday morning, a luncheon conference, and a banquet Saturday evening at which the Banting Memorial Medal will be presented to Dr. Cyril N. H. Long, sterling professor of physiological chemistry, Yale University School of Medicine, New Haven, Conn. Dr. Long will present the Banting Memorial Lecture Saturday afternoon on "The Endocrine Control of the Blood Sugar." An address will be presented by Gerald L. Wendt, Ph.D., New York, on "The Interpretation of Scientific Progress." The annual business meeting will be held Sunday morning.

Cancer Society Plans More Clinics.—The American Cancer Society announced in March plans to increase by 150 per cent the number of cancer detection and treatment clinics. At least 900 more are needed to provide one center for every 100,000 population. There are now 609 such centers, according to Dr. Charles S. Cameron, medical director. The society will equip the clinics, provide supplies and operating facilities and help form a cancer group from the regular hospital staff in any locality. Only two states have enough cancer clinics to meet the society's population formula, Dr. Cameron said. They are Connecticut, with 23 centers for its over 2,000,000 residents, and New Hampshire, which has 11 facilities and a population of 533,000. Twelve of the nation's 609 cancer services are cancer hospitals, 470 are cancer clinics in hospitals, 120 are cancer diagnostic clinics and seven are departmental cancer clinics in other institutions.

Western Institute on Epilepsy.—The third Western Institute on Epilepsy will be held in Salt Lake City, June 15-17. The program is presented as a memorial to Dr. Jerry C. Price, formerly associated with the Neurological Institute in New York and vice president of the National Association to Control Epilepsy. Dr. Tracy Putnam, Beverly Hills, Calif., will speak on "The Evolution and Future of the Treatment of Epilepsy." Besides demonstrations and scientific papers, there will be a symposium on the therapeutic considerations under the chairmanship of Dr. Louis S. Goodman, University of Utah School of Medicine, Salt Lake City. Other participants will be Dr. Richard R. Carter, Portland, Ore., and Dr. Jean P. Davis, Salt Lake City. Registration fee for all physicians is $5 and for others $3, which includes the luncheon on Saturday. Applications should be sent to: Chairman, Western Institute on Epilepsy, Department of Psychiatry, Salt Lake General Hospital, 156 Westminster Ave., Salt Lake City.

American Therapeutic Society.—The 52d annual meeting of the American Therapeutic Society will be held at the Chalfonte-Haddon Hall, Atlantic City, N. J., June 8-10 under the presidency of Dr. James A. Lyons, Washington, D. C. An address of welcome will be presented by Dr. Anthony G. Meredino, president of the Atlantic County Medical Society. Among the speakers on the scientific program are: Drs. George L. Waldbott, Detroit; Z. T. Bercovitz, New York; L. Clagett Beck, Honolulu, Hawaii; Anthony Bassler, New York; Ernest A. Spiegel and Henry T. Wycis, Philadelphia; Francis M. Pottenger, Monrovia, Calif.; W. Wayne Babcock, Philadelphia; Benjamin Manchester, Washington, D. C.; Howard Wakefield and Willis G. Diffenbaugh, Chicago; Alphonse McMahon, St. Louis; Louis Faugeres Bishop Jr., and Milton R. Beyers, New York; Frank W. Konzelmann, Washington, D. C.; Paul Cutler, Atlantic City, N. J.; David I. Macht, Baltimore; Herbert S. Kupperman and Stanley J. Goodman, New York; Hollis K. Russell, Scarsdale, N. Y., and Oscar B. Hunter Jr., Washington, D. C. The president's reception will be held Saturday evening, followed by the banquet at which the speaker of the evening will be Dr. Jonathan Forman, Columbus, Ohio, editor of the *Ohio State Medical Journal.*

Colonel Tuttle to Retire.—Col. Arnold D. Tuttle, who pioneered medical research as related to commercial air transportation, has announced his retirement from United Air Lines, effective June 1. He will be succeeded by Dr. George J. Kidera. Col. Tuttle served in France during World War I, supervised the reorganization of the Army medical department, and served as commandant of the Army School of Aviation Medicine at Randolph Field, Texas. He joined United in 1937 to undertake a long-range project of applying medical research and techniques to commercial air transportation. He holds the 1949 John Jeffries award of the Institute of Aeronautical Sciences for "outstanding contributions to the advancement of aeronautics through medical research." His military decorations include the Distinguished Medal, French Legion of Honor, and Belgian Order of Leopold. Dr. Kidera, with United since 1939, served four years as an Air Force flight surgeon, then returned to United in 1946 as head of the company's Chicago medical branch.

Foundation Prize.—The American Association of Obstetricians, Gynecologists and Abdominal Surgeons will award its Foundation Prize of $200 at the annual meeting of the association, at which time the successful contestant must appear in person to present his contribution as a part of the regular scientific program. Eligible contestants shall include only (a) interns, residents or graduate students in obstetrics, gynecology or abdominal surgery, and (b) persons with an M.D. degree or a scientific degree approved by the Prize Award Committee, who are actively practicing or teaching obstetrics, gynecology or engaged in research in these fields. Manuscripts must be presented under a nom de plume, which shall in no way indicate the author's identity, to the secretary of the association together with a sealed envelope bearing the nom de plume and containing a card showing the name and address of the contestant. Manuscripts must be limited to 5,000 words and must be typewritten in double spacing on one side of the sheet. Ample margins should be provided.

World Birth Rates.—Birth rates throughout the world rose sharply shortly after the close of World War II and have continued at high levels during the postwar years, Metropolitan Life Insurance Company statisticians report. Most of the countries had higher birth rates during the war than in the years just before the war. In the United States, for example, the rates averaged 15 per cent higher in 1940-1944 than in 1937-1939, and in Austria, Sweden, Switzerland, and New Zealand the rise from the prewar to the war years was even more pronounced. These facts suggest that the postwar rise in births in many of the countries was due not so much to deferment of births during the war as to the improvement of economic conditions after the war. Although the world trend has been somewhat downward since 1947, when most countries reached their postwar birth rate peak, the declines generally have been slight. In the United States the 1949 rate was only 7 per cent lower than that for 1947, and the decreases have been even smaller in other countries, including Canada, the Union of South Africa, and Australia. Exceptions to this are England and Wales and the Netherlands, where the rates had declined markedly by 1949 from their postwar peaks. France, for many years prior to the war on the brink of a population decline, experienced an upsurge of births during the postwar years, which by 1947 had carried its birth rate to a point 43 per cent higher than the prewar level. Japan's 1947 birth rate was 22 per cent above the prewar figure, and the decline from 1947 through 1949 was only 3 per cent, although the first nine months of 1950 showed a sharp fall that may bring the 1950 rate close to the 1937-1939 level. Western Germany and Italy have departed from the general pattern. Western Germany's birth rate rose somewhat during the postwar years but remained well below the 1938 figure, and the Italian rate, after rising during 1945 and 1946, declined by 1949 to 15 per cent below that for the prewar period.

CANADA

Personal.—The Manufacturers Life Insurance Company, Toronto, has announced the appointment of Dr. David J. Breithaupt, Scarborough Junction, Ontario, as assistant medical officer.

Cleft Palate Rehabilitation.—A clinical and research project in caring for children and adults with cleft lip and palate was established during 1950 at the Royal Victoria Hospital in Montreal. *A grant of over $20,000 from the Department of Health* of the Province of Quebec, which will provide partial support, has been renewed for 1951. This program provides speech therapy in both French and English and offers training facilities for children and adults. A long term research investigation into the value of various types of therapy will be carried out. Experimental work on animals, already completed, has revealed data on the role of environmental factors in causation of cleft palate. The speech pathologist in charge of speech therapy is Mr. Robert Sparks, M.A., formerly of Stanford University, San Francisco.

FOREIGN

Medical Education Team for Japan.—The organization of the third medical education team for Japan has been undertaken by the Unitarian Service Committee with the approval of the Supreme Command Allied Powers. Four teams of three men each will spend a period of two weeks in three different medical schools between May 14 and July 1. The medical education team is composed of Drs. Paul B. Beeson, Atlanta; Lauren V. Ackerman, St. Louis; Daniel C. Darrow, New Haven, Conn.; Charles S. Davidson, Boston; Charles G. Johnston, Detroit; Philip Handler, Ph.D., Durham, N. C.; Drs. Salvatore P. Lucia and Robert R. Newell, San Francisco; Malcolm H. Soule and Maurice H. Seevers, Ann Arbor, Mich., and Perry P. Volpitto, Augusta, Ga. A second surgeon will be included.

British South African Meeting Cancelled.—The annual scientific meeting of the British Medical Association, which was to have been held in South Africa, has been cancelled due to circumstances outside the control of the Association. Arrangements have now been made jointly by the Royal Society of Medicine and the British Medical Association for a series of scientific meetings to be held throughout June at One Wimpole St., London, W. 1. This scientific meeting will consist of symposiums introduced by eminent authorities on subjects of special interest under the general heading of "Medicine in Britain in the Festival Year, 1951—Its Achievements and Its Future." These meetings are open to all medical practitioners. A cordial invitation has been extended to members of the American Medical Association.

First Children's Hospital in Bolivia.—An agreement providing for technical assistance from the World Health Organization in the construction, equipping, and organization of the first children's hospital in Bolivia has been signed by the minister of health of Bolivia and the director of WHO's regional office for the Americas. The $500,000, 240-bed hospital already under construction in La Paz is scheduled for completion in 1952. The United Nations International Children's Emergency Fund has earmarked $75,000 for equipment and supplies. The World Health Organization has set aside $40,000 for the training of *professional and technical personnel for the hospital's* staff. Fellowships will be awarded by WHO for the postgraduate and technical training of four pediatricians, three pediatric nurses, and one each of the following: radiologist, pathologist, anesthetist, director of nurses, operating room supervisor, *hospital administrator*, hospital accountant, laundry manager, maintenance engineer, and medical librarian. The fellowship recipients will be selected by the Bolivian Ministry of Health and will receive training in medical institutions in the United States and Latin American countries. The new children's hospital will be used as the foundation for a comprehensive program for child health services in Bolivia and will serve also as a training center for pediatricians, pediatric nurses, social workers, and other personnel engaged in child health and welfare.

MEETINGS

American Medical Association, Atlantic City, June 11 to 15. Dr. George F. Lull, 535 N. Dearborn St., Chicago 10, Secretary.

American College of Chest Physicians, Atlantic City, June 7-10. Mr. Murray Kornfeld, 500 N. Dearborn St., Chicago 10, Executive Secretary.

American College of Radiology, Atlantic City, June 10. Mr. W. C. Stronach, 20 N. Wacker Drive, Chicago 6, Executive Secretary.

American Diabetes Association, Chalfonte-Haddon Hall, Atlantic City, June 9-10. Dr. John A. Reed, 11 W. 42d St., New York 18, Secretary.

American Electroencephalographic Society, Hotel Claridge, Atlantic City, June 16-17. Dr. John A. Abbott, Massachusetts General Hospital, Boston 14, Secretary.

American Hearing Society, Palmer House, Chicago, June 29. Mrs. Frances E. Lee, 817 Fourteenth St. N.W., Washington 5, D. C., Secretary.

American Medical Women's Association, Hotel Dennis, Atlantic City, June 9-11. Dr. Mildred C. J. Pfeiffer, *Woman's Medical College of* Pennsylvania, Philadelphia 29, Secretary.

American Neurological Association, Atlantic City, June 18-20. Dr. H. Houston Merritt, 710 W. 168th St., New York 32, Secretary.

American Orthopedic Association, The Greenbrier, White Sulphur Springs, W. Va., June 20-23. Dr. C. Leslie Mitchell, Henry Ford Hospital, Detroit 2, Secretary.

American Proctologic Society, Atlantic City, June 7-10. Dr. W. Wendell Green, 1838 Parkwood Ave., Toledo 2, Ohio, Secretary.

American Society for the Study of Sterility, Ritz-Carlton Hotel, Atlantic City, June 9-10. Dr. John O. Haman, 490 Post St., San Francisco 2, Secretary.

American Therapeutic Society, Atlantic City, June 8-10. Dr. Oscar B. *Hunter, 915 Nineteenth St. N.W., Washington 6, D C., Secretary.*

Conference of Presidents and Other Officers of State Medical Associations, Hotel Traymore, Atlantic City, June 10. Mr. John E. Farrel, 106 Francis St., Providence 3, R. I., Secretary.

Great Falls Medical-Surgical Conference, Great Falls, Montana, June 25-26. Dr. William E. Sullens, Box 1066, Great Falls, Chairman.

Idaho State Medical Association, Sun Valley, June 17-20. Dr. Robert S. McKean, 305 Sun Building, Boise, Secretary.

Maine Medical Association, Poland Spring House, Poland Spring, June 17-19. Dr. Frederick R. Carter, 142 High St., Portland 3, Secretary.

Medical Library Association, Denver, June 28-30. Miss Caroline Riechers, Rush Medical College Library, 1758 W. Harrison St., Chicago 12, Secretary.

Post Graduate Medical Assembly of South Texas, Shamrock Hotel, Houston, Texas, July 23-25. Mrs. W. H. Dahme, 229 Medical Arts Bldg., Houston, Executive Secretary.

Society for Vascular Surgery, Chalfonte-Haddon Hall, Atlantic City, June 10. Dr. George D. Lilly, 333 Ingraham Bldg., Miami 32, Fla., Secretary.

Society of Biological Psychiatry, Claridge Hotel, Atlantic City, June 17. Dr. George N. Thompson, 1136 W. Sixth St., Los Angeles 17, Secretary.

West Virginia State Medical Association, The Greenbrier, White Sulphur Springs, July 19-21. Mr. Charles Lively, 1031 Quarrier St., Charleston 24, Executive Secretary.

INTERNATIONAL

European Congress on Rheumatism, Barcelona, Spain, Sept. 24-27. Dr. Gunnar Edströn, Lund, Sweden, Secretary.

General Practitioners Study Club International, Rome, Italy, Sept. 12-15. Dr. John O'Connell, 10300 Lackland Road, St. Louis 14, Mo., U. S. A., President.

International Anesthesia Research Society, London, England, Sept. 3-7. Mr. R. W. Cope, University College Hospital, London W.C.1, England.

International Association of Allergists, Zurich, Switzerland, Sept. 23-29. Prof. A. S. Grumbach, Hygiene Institut der Universitaet Zurich, Gloriastr. 32, Zurich, Switzerland.

International Congress of Anesthesiology, Nursing School of the Salpiettre, 47 Boul de l'Hospital, Paris, France, Sept. 20-22. 12 rue de Seine, Paris 6^{e}, France, Secretariat.

International Congress of Clinical Pathology, London, England, July 16-20. Dr. W. H. McMenemey, Maida Vale Hospital for Nervous Diseases, London W.9, England, Secretary.

International Congress of Gynecology, Maison de la Chimie, Centre Marcellin, Paris, France, June 23-29. Dr. Maurice Fabre, 1, rue Jules-Lefebvre, Paris IX, General Secretary.

International Congress on Industrial Medicine, Instituto Superior Técnico, Lisbon, Portugal, Sept. 9-15. Dr. Luis Guerreiro, Instituto Nacional do Trabalho e Previdência, Praça do Comercio, Lisbon, Secretary General.

International Congress on Mental Health, Mexico City, Mexico, Dec. 11-19.

International Congress of Military Medicine and Pharmacy, Paris, France, June 17-23. Physician General Dutrey, 8, bis, rue de Recollets, Paris X, Secretary General.

International Exhibition of Medical Arts, Turin, Italy, May 30-June 12. Prof. S. Teneff, Palazzo della Exposizioni al Valentino, Turino, Italy.

International Gerontological Congress, Hotel Jefferson, St. Louis, Mo., U. S. A., Sept. 9-14. Dr. John E. Kirk, 5600 Arsenal Street, St. Louis 9, Mo., Chairman, Program Committee.

International Hospital Congress, Brussels, Belgium, July 15-21. Capt. J. E. Stone, 10 Old Jewry, London E.C., England, Secretary.

International Poliomyelitis Congress, Copenhagen, Denmark, Sept. 3-7. Prof. Dr. Niels Bohr, Statens Seruminstitut, 80 Amager Blvd., Copenhagen S., Denmark, President.

International Society of Surgery, Paris, France, Sept. 24-29. Dr. L. Dejardin, 141, rue Belliard, Brussels, Belgium, Secretary General.

International Society for the Welfare of Cripples, Fifth World Congress, Stockholm, Sweden, Sept. 9-14. Mr. Donald V. Wilson, 54 E. 64th St., New York 21, N. Y., U. S. A., Executive Director.

Pan Pacific Surgical Association Congress, Honolulu, Hawaii, Nov. 7-19. Dr. Forrest J. Pinkerton, Suite 7, Young Bldg., Honolulu, Hawaii, President.

Students' International Clinical Congress, Leyden, Utrecht, Groningen and Amsterdam, Holland, July 10-28. N. A. M. Bergstein, Oude Gracht 143 bis, Utrecht, Holland, Secretary General.

World Confederation for Physical Therapy, Copenhagen, Denmark, Sept. 7-8.

World Medical Association, Stockholm, Sweden, Sept. 15-21. Dr. Louis H. Bauer, 2 E. 103d St., New York 29, N. Y., U. S. A., Secretary-General.

EXAMINATIONS AND LICENSURE

BOARDS OF MEDICAL EXAMINERS

Alabama: Montgomery, June 26-28. Sec., Dr. D. G. Gill, 519 Dexter *Ave., Montgomery.*

Arizona:* *Examination.* Phoenix, July 17-19. *Reciprocity.* Phoenix, July 21. Sec., Dr. J. H. Patterson, 316 W. McDowell Road, Phoenix.

Arkansas: * *Regular.* Little Rock, June 14-15. Sec., Dr. Joe Verser, Harrisburg. *Homeopathic.* Fort Smith, June 7-8. Sec., Dr. Carl S. Bungart, 105 N. 14th St., Fort Smith. *Eclectic.* Little Rock, June 7-8. Sec., Dr. C. H. Young, 1415 Main St., Little Rock.

California: *Written.* San Francisco, June 25-28 and Aug. 20-23. *Oral.* San Francisco, June 23 and Los Angeles, August 18. *Oral and Clinical Examination for Foreign Medical School Graduates.* San Francisco, June 24 and Los Angeles, August 19. Sec., Dr. Frederick N. Scatena, 1020 N St., Sacramento 14.

Colorado:* *Examination.* Denver, June 18-20. *Reciprocity.* Denver, July 10. Sec., Dr. George H. Gillen, 831 Republic Bldg., Denver 2.

Connecticut:* *Regular. Examination.* Hartford, July 10-11. Sec. to the Board, Dr. Creighton Barker, 160 St. Ronan St., Hartford. *Homeopathic.* Derby, July 11-12. Sec., Dr. Donald A. Davis, 38 Elizabeth St., Derby.

Delaware: *Examination.* Dover, July 10-12. *Reciprocity.* Dover, July 19. Sec., Dr. J. S. McDaniel, 229 S. State St., Dover.

District of Columbia:* *Reciprocity.* Washington, June 11. Sec., Dr. Daniel L. Seckinger, 4130 East Municipal Bldg., Washington.

Florida:* *Examination.* Jacksonville, June 24-26. Sec., Dr. Homer L. Pearson, 701 DuPont Bldg., Miami.

Georgia: Atlanta, June. Augusta, June. Sec., Mr. R. C. Coleman, 111 State Capitol, Atlanta.

Guam: The Commission on Licensure will meet whenever a candidate appears or submits his credentials. Ex. Sec., Dr. John Y. Battenfield, Agana.

Hawaii: *Examination.* Honolulu, July 9-12. Sec., Dr. I. L. Tilden, 1020 Kapiolani St., Honolulu.

Idaho: Boise, July 9-11. Sec., Mr. Armand L. Bird, 305 Sun Bldg., Boise.

Illinois: Chicago, June 26-28. Supt. of Regis., Mr. Charles F. Kervin, Capitol Bldg., Springfield.

Indiana: Indianapolis, June 20-22. Exec. Sec., Miss Ruth V. Kirk, 1138 K. of P. Bldg., Indianapolis 4.

Iowa: * *Written.* Iowa City, June 11-13. Sec., Dr. M. A. Royal, 506 Fleming Bldg., Des Moines.

Kansas: Kansas City, June 6-7. Sec., Dr. O. W. Davidson, 864 New Brotherhood Building, Kansas City.

Kentucky: Louisville, June 6-8. Sec., Dr. Bruce Underwood, 620 S. 3rd St., Louisville.

Louisiana: New Orleans, June 7-9. Sec., Dr. Roy B. Harrison, 1507 Hibernia Bank Bldg., New Orleans 12.

Maine: Augusta, July 10-11. Sec., Dr. Adam P. Leighton, 192 State St., Portland.

Maryland: Baltimore, June 19-22. Sec., Dr. Lewis P. Gundry, 1215 Cathedral St., Baltimore 1. *Homeopathic.* Baltimore, June 19-20. *Examination.* Sec., Dr. John A. Evans, 612 W. 40th St., Baltimore.

Massachusetts: *Examination.* Boston, July 10-13. Sec., Dr. Robert C. Cochrane, Room 37, State House, Boston 33.

Michigan:* *Examination.* Ann Arbor and Detroit, June 11-13. Sec., Dr. J. Earl McIntyre, 203 Hollister Bldg., Lansing.

Minnesota:* Minneapolis, June 19-21. Sec., Dr. J. F. DuBois, 230 Lowry Medical Arts Bldg., St. Paul 2.

Mississippi: Jackson, June. Asst. Sec., Dr. R. N. Whitfield, Jackson 113.

Missouri: St. Louis, June 7-9. Exec. Sec., Mr. John A. Hailey, Box 4, State Capitol Bldg., Jefferson City.

Nebraska: * June 1951. Director, Mr. Oscar F. Humble, Room 1009, State Capitol Bldg., Lincoln.

Nevada:* Carson City, August 6. Sec., Dr. G. H. Ross, 112 North Curry St., Carson City.

New Hampshire: Concord, Sept. 12-13. Sec., Dr. John Samuel Wheeler, Room 107 State House, Concord.

New Jersey: *Examination.* Trenton, June 19-22. Sec., Dr. E. S. Hallinger, 28 W. State St., Trenton.

New Mexico:* Santa Fe, Oct. 8-9. Sec., Dr. Charles J. McGoey, Coronado Bldg., Santa Fe.

New York: Albany, Buffalo, New York and Syracuse, June 26-29. Sec., Dr. Jacob L. Lochner, Jr., 23 S. Pearl St., Albany 7.

North Carolina: *Endorsement.* Raleigh, June 18-21. Sec., Dr. Joseph J. Combs, 419 Professional Bldg., Raleigh.

North Dakota: Grand Forks, *July 4-7. Sec., Dr. C. J. Glaspel, Grafton.*

Ohio: *Examination.* Columbus, June 19-21. *Endorsement.* Columbus, April 3. Sec., Dr. H. M. Platter, 21 W. Broad Street, Columbus.

Oklahoma: * *Examination.* Oklahoma City, June 6-7. Sec., Dr. Clinton Gallaher, 813 Braniff Bldg., Oklahoma City.

Oregon:* *Examination.* Portland, June 21-23. Special examination for physicians who have orders to report for military service about July 1. *Examination.* Portland, July 5-7. Sec., Mr. Howard I. Bobbitt, 609 Failing Bldg., Portland 4.

Pennsylvania: *Examination.* Philadelphia and Pittsburgh, July 10-13. Acting Sec., Mrs. M. G. Steiner, 351 Education Bldg., Harrisburg.

Puerto Rico: *Examination.* Santurce, Sept. 4. Sec., Mr. Luis Cueto Coll, Box 3717, Santurce.

Rhode Island:* *Examination.* Providence, July 5-6. Administrator of Professional Regulation, Mr. Thomas B. Casey, 366 State Office Bldg., Providence.

South Carolina: *Examination.* Columbia, June 25-27. *Reciprocity.* Columbia, April 2 and May 15. Sec., Dr. N. B. Heyward, 1329 Blanding St., Columbia.

South Dakota: Rapid City, July 17-18. Sec., Dr. Clarence E. Sherwood, 109 Center St., West, Madison.

Tennessee:* *Examinaiton.* Memphis and Nashville, June 13-14. Sec., Dr. H. W. Qualls, 1635 Exchange Bldg., Memphis 3.

Texas:* *Examination.* Austin, June 14-16. Sec., Dr. M. H. Crabb, 1714 Medical Arts Bldg., Fort Worth 2.

Utah: Salt Lake City, July 11-13. Asst. Dir., Mr. Frank E. Lees, 324 State Capitol Bldg., Salt Lake City 1.

Vermont: *Examination.* Burlington, June 13-15. Sec., Dr. F. J. Lawliss, Richford.

Virginia: *Examination.* Richmond, June 14-16. Sec., Dr. K. D. Graves, *631 First St., S.W., Roanoke.*

Virgin Islands: St. Thomas, June 12. Sec., Dr. Earle M. Rice, St. Thomas.

Washington:* Seattle, July 16-18. Sec., Department of Licenses, Mr. Edward C. Dohm, Olympia.

West Virginia: Charleston, July 9-11. Sec., Dr. N. H. Dyer, Capitol Bldg., Charleston 5.

Wisconsin:* Milwaukee, July 10-12. Sec., Dr. C. A. Dawson, River Falls.

Wyoming: *Examination.* Cheyenne, June 4. Sec., Dr. Franklin D. Yoder, Capitol Bldg., Cheyenne.

BOARDS OF EXAMINERS IN THE BASIC SCIENCES

Alaska: Juneau, August. Sec., Dr. C. Earl Albrecht, Box 1931, Juneau.

Arizona: *Examination.* Tucson, June 19. Sec., Mr. Francis A. Roy, Room 427, University of Arizona, Tucson.

Colorado: *Examination.* Denver, June 6-7. Sec., Dr. Esther B. Starks, 1459 Ogden St., Denver. 3.

Connecticut: *Examination.* New Haven, June 9. Exec. Asst., Miss Mary G. Reynolds, State Board of Healing Arts, 110 Whitney Ave., New Haven.

District of Columbia: *Examination.* Washington, Oct. 22-23. Sec., Dr. Daniel L. Seckinger, 4130 E. Municipal Bldg., Washington.

Florida: *Examination.* Gainesville, June 2. Sec., Mr. M. W. Emmel, University of Florida, Gainesville.

Iowa: *Examination.* Des Moines, July 10. Sec., Dr. Ben H. Peterson, Coe College, Cedar Rapids.

Minnesota: *Examination.* Minneapolis, June 5-6. Sec., Dr. Raymond N. Bieter, 105 Millard Hall, University of Minnesota, Minneapolis 14.

Nevada: *Examination.* Reno, July 3. Sec., Mr. Frank Robinson, University of Nevada, Reno.

New Mexico: *Examination.* Santa Fe, June 17. *Sec., Miss Marguerite Cantrell,* Box 1522, Santa Fe.

Oklahoma: Oklahoma City, Sept. 14. *Sec., Dr. Frank C. Gallaher,* 813 Braniff Bldg., Portland 4.

Oregon: *Examination.* Portland, June 2, Sept. 8 and Dec. 1. Sec., Dr. Charles D. Byrne, State Board of Higher Education, University of Oregon, Eugene.

South Dakota: *Examination.* Vermillion, June 15-16. Sec., Dr. Gregg M. Evans, 310 E. 15th St., Yankton.

Tennessee: *Examination. Memphis, July 5-6.* Sec., Dr. O. W. Hyman, 874 Union Ave., Memphis.

Texas: *Examination.* Austin, October. Chief Clerk, Mr. B. H. Kirk, 306 Nalle Bldg., Austin.

Washington: *Examination.* Seattle, July 11-12. Sec., Department of Licenses, Mr. Edward C. Dohm, Olympia.

---

* Basic Science Certificate required.

DEATHS

Jones, William Russell ⊕ Richmond, Va.; born in Orange County, Va., Jan. 18, 1870; University of Virginia Department of Medicine, Charlottesville, 1892; professor of chemistry, toxicology, and medical jurisprudence from 1897 to 1906, lecturer in clinical medicine and associate professor of medicine from 1906 to 1912 at his alma mater, where he had been a member of the board of directors and a trustee; at one time associated with the U. S. Public Health Service; member of the Richmond Academy of Medicine, Chesapeake and Ohio Association of Railway Surgeons, and the Association of Military Surgeons of the United States; chief surgeon and major in the medical corps of the Virginia National Guard in 1926; formerly consulting medical officer of the U. S. Chambers, William ⊕ Vice Admiral, U. S. Navy, retired, La Jolla, Calif.; born in Philadelphia Aug. 25, 1884; Jefferson Medical College of Philadelphia, 1907; commissioned a lieutenant (jg) in the medical corps of the U. S. Navy in 1908; served aboard the *USS Maryland, Lexington,* and *Galveston,* and with the Marine Corps, Atlantic Fleet Marine Expeditionary Forces, 13th Marine Regiment, and the Marine Guard, Peking, China; in 1926 was designated a flight surgeon; in 1933-1934 was a member of the American Scientific Mission to Haiti; medical officer in command of the Naval Hospital, Canacao, P. I., from 1935 to 1938, Naval Medical School, Washington, D. C., from 1938 to 1940, Naval Hospital, San Diego, from 1940 to 1942, and the National Naval Medical Center, Bethesda, Md., from 1944 to 1946; was district medical officer of the 14th Naval District then became inspector of the medical department activities of the Pacific area from 1942 to 1944; for his outstanding duties in this assignment received the Distinguished Service Medal; retired on Nov. 1, 1946; fellow of the American College of Surgeons; died in the U. S. Naval Hospital March 29, aged 66, of cerebral hemorrhage.

Sanderson, Edward Theodore, Alexandria, Minn.; born in Boone, Iowa, April 20, 1875; Bennett Medical College, Chicago, 1905; member of the American Medical Association; formerly professor of anatomy at his alma mater, where he had been secretary and registrar; appointed to the first state advisory commission on tuberculosis in 1917; in 1922 was appointed to the state board of medical examiners and remained on the board until 1932; past president of the Lyon-Lincoln Counties Medical Society; awarded citations and medals from the Presidents of the United States for the examination of selectees in World Wars I and II; served as mayor and councilman of Alexandria and for many years member and president of the school board; on the staff of the Marshall (Minn.) Hospital; died March 16, aged 75, of cerebral thrombosis.

Hirsh, Maurice, Patton, Calif.; Friedrich-Wilhelms-Universität Medizinische Fakultät, Berlin, Prussia, Germany, 1913; formerly affiliated with Jewish Consumptive Relief Society Sanatorium, Denver; for many years chief resident physician and assistant medical director of Duarte National Medical Center in Duarte; affiliated with Patton State Hospital; served on the staff of the Los Angeles Sanatorium in Duarte, where he died Feb. 27, aged 62, of bronchogenic carcinoma following left pneumonectomy.

Abington, W. H. Beebe, Ark.; Memphis Hospital Medical College, 1896; state senator; also a druggist; died March 19, aged 80.

Althans, Carl ⊕ St. Louis; Washington University School of Medicine, St. Louis, 1903; died April 1, aged 69, of myocardial infarction.

Banach, Leon, Jersey City, N. J.; Chicago College of Medicine and Surgery, 1915; died in the B. S. Pollak Hospital for Chest Diseases March 14, aged 65, of coronary thrombosis.

Benn, Ferdinand George ⊕ La Mesa, Calif.; Minneapolis College of Physicians and Surgeons, 1903; member of the Minnesota State Medical Association; an Associate Fellow of the American Medical Association; died March 12, aged 72.

Blackwell, Samuel R., Gary, Ind.; Meharry Medical College, Nashville, Tenn., 1913; died in the Methodist Hospital March 4, aged 69, of pneumonia and myocardial failure.

Burnett, James Robinet ⊕ Caldwell, Kan.; Kansas Medical College, Medical Department of Washburn College, Topeka, 1912; on the staff of the Caldwell General Hospital; died Feb. 23, aged 70.

Chandler, John Franklin, Oregon, Mo.; Kansas City Medical College, 1895; member of the American Medical Association; died in St. Joseph Feb. 19, aged 84, of bronchopneumonia.

Clegg, Earl George, Sheridan, Wyo.; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1910; served on the staff of the Sheridan County Memorial Hospital, where he died March 31, aged 70, of cerebral hemorrhage.

Coffey, J. O., Queen City, Mo.; Missouri Medical College, St. Louis, 1885; for many years member of the school board; died March 25, aged 87.

Conover, Earl, Evansville, Ind.; University of Louisville Medical Department, 1905; served on the staffs of St. Mary's Hospital and the Deaconess Hospital, where he died March 25, aged 72, of cardiovascular renal disease.

Dainty, George Wood ⊕ Monument Beach, Mass.; Tufts College Medical School, Boston, 1907; for many years chairman of the school committee in Bourne; on the consulting staff and a director of the Barnstable County Sanatorium in Bourne; on the consulting staffs of the Cape Cod Hospital in Hyannis and Tobey Hospital in Wareham; died March 24, aged 66, of chronic nephritis, uremia and rheumatoid arthritis.

Dougherty, Lewis Edwin, Canton, Ohio; Ohio State University College of Medicine, Columbus, 1924; member of the American Medical Association; died Feb. 20, aged 54, of acute myocardial infarction.

Dowling, Joseph Ivimey, Albany, N. Y.; born in Woodside, N. J., Dec. 22, 1872; New York Homeopathic Medical College, New York, 1895; member of the American Medical Association and the American Academy of Ophthalmology and Otolaryngology; fellow of the American College of Surgeons; specialist certified by the American Board of Ophthalmology; medical health inspector for the health department of New York City from 1896 to 1898; served on the staff of the Memorial Hospital; died March 22, aged 78, of arteriosclerotic heart disease.

Duhamel, Oliver Gilbert, Marlboro, Mass.; School of Medicine and Surgery of Montreal, Canada, 1894; for many years city physician; on the staff of the Marlboro Hospital; died March 28, aged 81, of cerebral hemorrhage.

Dulaney, Henry Kennedy, Aberdeen, Md.; Atlantic Medical College, Baltimore, 1910; member of the American Medical Association; died Feb. 10, aged 69.

Dyas, Thomas C., New York; University and Bellevue Hospital Medical College, New York, 1911; died in the Roosevelt Hospital March 11, aged 77, arteriosclerotic heart disease with aortic stenosis.

⊕ Indicates Fellow of the American Medical Association.

Englander, Simon ⊕ Cleveland; Western Reserve University Medical Department, Cleveland, 1901; served on the staffs of the Lakeside and St. Vincent Charity hospitals; died March 5, aged 71, of coronary thrombosis.

Enochs, Robert Jones, Hayden, Colo.; Medical Department of Tulane University of Louisiana, New Orleans, 1909; member of the American Medical Association; for many years associated with the Indian Service; resident physician at the Montana State Tuberculosis Sanitarium in Deer Lodge; died in the French Hospital, San Francisco, March 15, aged 68, of cerebrovascular accident.

Face, Edward Gill Jr. ⊕ Richmond, Va.; University of Virginia Department of Medicine, Charlottesville, 1941; interned at the University of Virginia Hospital in Charlottesville; served during World War II; died March 6, aged 34.

Fairbanks, Clark Vernon, Dansville, N. Y.; University of Buffalo School of Medicine, 1896; served during World War I; died March 23, aged 78, of cerebral hemorrhage.

Farmer, Robert Allen, Grapeland, Texas; University of Texas School of Medicine, Galveston, 1910; died in Crockett recently, aged 68, of injuries received in an automobile accident.

Fellows, Frederick Brown, Wheaton, Ill.; Chicago College of Medicine and Surgery, 1914; member of the American Medical Association; medical examiner in World War I; died in the Elmhurst Memorial Hospital March 4, aged 85, of ulcer of the duodenum and hiatus hernia.

Flamm, Louis Francis, Muskogee, Okla.; Maryland Medical College, Baltimore, 1902; also a dentist; died in Temple, Texas, Feb. 22, aged 86, of carcinoma of the intestine.

Friis-Holm, Gudrun, Long Beach, Calif.; New York Medical College and Hospital for Women, Homeopathic, 1904; died in the Los Angeles County General Hospital Jan. 15, aged 83, of hemorrhage and carcinoma of the bladder.

Fudema, John Joseph, Chicago; Bennett Medical College, Chicago, 1914; died March 22, aged 63, of coronary thrombosis and hypertension.

Fuller, Frederick Henry, Walpole, Mass.; Harvard Medical School, Boston, 1894; member of the American Medical Association; served as school physician and health officer; died March 9, aged 80, of arteriosclerosis and pneumonia.

Garvin, Luke Denis ⊕ Bradford, Pa.; Northwestern University Medical School, Chicago, 1934; served during World War II; affiliated with Bradford Hospital; found in the Allegheny River in Salamanca, N. Y., March 18, aged 48.

Gilfillan, George William ⊕ Bloomfield, Iowa; State University of Iowa College of Medicine, Iowa City, 1924; served during World War II; on the staff of St. Joseph Hospital in Ottumwa, where he died March 28, aged 51, of periarteritis nodosa.

Goldwater, Abraham Lincoln ⊕ New York; Bellevue Hospital Medical College, New York, 1897; died March 23, aged 79, of cerebral thrombosis.

Grace, John Franklin, Excelsior Springs, Mo.; Medico-Chururgical College of Kansas City, 1903; member of the American Medical Association; served during World War I; member of the city board of health; served on the city council and school board; on the staff of the Excelsior Springs Sanitarium and Hospital; died in the Veterans Administration Hospital, Wadsworth, March 3, aged 72, of carcinoma of the stomach.

Greenleaf, Clarence Albert, Olean, N. Y.; Columbia University College of Physicians and Surgeons, New York, 1896; member of the American Medical Association; past president of the New York State Association of School Physicians; medical director of the school system and director of the county school hygiene service; served during World War I; died in the Memorial Hospital, New York, March 4, aged 78.

Gronoway, Terrence Ponderley ⊕ Macon, Mo.; Washington University School of Medicine, St. Louis, 1910; died March 7, aged 63, of coronary thrombosis.

Hanson, Kenneth Boccarde ⊕ Cincinnati; University and Bellevue Hospital Medical College, New York, 1930; member of the American Association of Industrial Physicians and Surgeons; fellow of the American College of Surgeons; served during World War II; affiliated with St. Francis, Good Samaritan, Our Lady of Mercy, and St. Mary's hospitals; died in Rome, Italy, March 22, aged 45, of cerebral hemorrhage.

Hartin, David, Spokane, Wash.; McGill University Faculty of Medicine, Montreal, Canada, 1914; member of the American Medical Association and the Pacific Coast Oto-Ophthalmological Society; served overseas with the Canadian Army during World War I; died March 9, aged 59, of coronary occlusion.

Hastings, Seman Wood ⊕ Monterey, Calif.; University of Southern California School of Medicine, Los Angeles, 1908; died recently, aged 73, of heart disease.

Haury, Richard Samuel, Newton, Kan.; Northwestern University Medical School, Chicago, 1902; fellow of the American College of Surgeons; served as a member of the state board of health; for many years a director of the Midland National Bank; affiliated with Bethel Deaconess Hospital, where he died March 16, aged 78, of hypertension, arteriosclerosis, and cerebral hemorrhage.

Hay, Gilbert W., Parsons, Kan.; Chicago College of Medicine and Surgery, 1913; member of the American Medical Association; served on the staff of the Mercy Hospital, where he died March 3, aged 74, of cerebral hemorrhage.

Helbing, Arlington, San Angelo, Texas; American Medical College, St. Louis, 1905; member of the American Medical Association; local surgeon for the Santa Fe Railroad; affiliated with Shannon, West Texas Memorial, and St. John's hospitals; died Jan. 24, aged 68, of acute coronary occlusion.

Hibbard, Samuel M., Sabetha, Kan.; Ensworth Medical College, St. Joseph, Mo., 1907; member of the American Medical Association; veteran of World War I; later a lieutenant colonel in the medical reserve corps (not on active duty); served as mayor; on the staff of St. Anthony Murdock Memorial Hospital; died in Veterans Administration Hospital, Topeka, March 7, aged 65, of coronary thrombosis.

Holding, Solomon Pace, Wake Forest, N. C.; Bellevue Hospital Medical College, New York, 1897; at one time mayor of Wake Forest; died March 3, aged 79, of coronary thrombosis.

Holloman, Thomas Bascom, Itta Bena, Miss.; Memphis Hospital Medical College, 1898; member of the American Medical Association; died March 28, aged 76.

Houston, Albert Joshua, Beverly Hills, Calif.; Cooper Medical College, San Francisco, 1898; member of the American Medical Association; clinical professor of otology, rhinology, and laryngology emeritus at the University of California Medical School, San Francisco; died March 28, aged 77.

Howard, John Edgar, Haddonfield, N. J.; Jefferson Medical College of Philadelphia, 1901; member of the American Medical Association; died in the Cooper Hospital, Camden, March 8, aged 75, of coronary thrombosis.

Howe, Warren D., Dorset, Vt.; Chicago Homeopathic Medical College, 1895; died in Daytona Beach, Fla., in March, aged 83, of cerebral thrombosis.

Hoyt, Charles Wentworth ⊕ Hingham, Mass.; Harvard Medical School, Boston, 1905; died Feb. 7, aged 71.

Hummel, Leonard Malcolm ⊕ Baltimore; University of Maryland School of Medicine and College of Physicians and Surgeons, Baltimore, 1934; died Feb. 7, aged 41.

Jacobs, Jay, San Francisco; Cooper Medical College, San Francisco, 1911; member of the American Medical Association; served during World War I; died in the Veterans Administration Hospital March 18, aged 62, of hypertensive encephalopathy.

Jayet, Albert Charles A., Santa Cruz, Calif.; University of Vermont College of Medicine, Burlington, 1889; past president of the Santa Clara County Medical Society; formerly practiced in San Jose, where he was city councilman; died March 11, aged 87.

Johnson, Burke Lamartine, Kenton, Ohio; Cleveland Medical College, Homeopathic, 1896; honorary president and for many years direector and president of the Kenton National Bank; died March 24, aged 77.

Knox, Charles Albert ⊕ Ridgefield Park, N. J.; Baltimore Medical College, 1904; died in the Hackensack (N. J.) Hospital March 9, aged 72, of coronary thrombosis.

Knudson, Theodore James, Springfield, Ill.; Northwestern University Medical School, Chicago, 1895; died April 14, aged 82.

Lartigau, August Jerome ⊕ Ojai, Calif.; University of California Medical School, San Francisco, 1896; fellow of the American College of Surgeons; an Associate Fellow of the American Medical Association; formerly on the staff of Children's Hospital in San Francisco; died in St. Francis Hospital, Santa Barbara, March 14, aged 76, of pneumonitis and arteriosclerotic heart disease.

Matteson, Herman Howard, Los Angeles (licensed in Wisconsin in 1900); surgeon of exploring parties in Central America, ship's surgeon, and surgeon at a federal penitentiary; died March 18, aged 76, of ruptured esophageal varix.

Mendenhall, William E. ⊕ Indianapolis; State College of Physicians and Surgeons, Indianapolis, 1907; died Feb. 20, aged 80, of coronary embolism.

Morrill, Leonard Brown ⊕ Center Harbor, N. H.; University of Vermont College of Medicine, Burlington, 1888; died March 17, aged 85, of chronic myocarditis.

Page, Willifred, Ellis, Kan.; Kansas Medical College, Medical Department of Washburn College, Topeka, 1907; served during World War I; died in Veterans Administration Center, Wichita, recently, aged 73, of arteriosclerotic heart disease.

Palisch, Gotthilf A., Agency, Mo.; Homeopathic Medical College of Missouri, St. Louis, 1896; died in Cape Girardeau March 15, aged 75, of acute coronary thrombosis and chronic myocarditis.

Plimpton, Robert Pearson, Denison, Iowa; Chicago Homeopathic Medical College, 1900; died in Riverside Hospital, Jacksonville, Fla., March 10, aged 79, of congestive heart failure and rheumatic fever.

Puckett, Charles Logan, St. Louis; St. Louis College of Physicians and Surgeons, 1904; member of the American Medical Association; died March 30, aged 72, of heart disease.

Rath, Otto A., Philadelphia; University of Pennsylvania Department of Medicine, Philadelphia, 1886; for many years associated with the Memorial Hospital, where he died March 9, aged 86.

Riker, John Lawrence, Rumson, N. J.; Columbia University College of Physicians and Surgeons, New York, 1930; served during World War II; died in Fair Oaks Sanatorium in Summit, Feb. 26, aged 46, of coronary thrombosis.

Rosier, John Bruner, Clarksburg, W. Va.; Jefferson Medical College of Philadelphia, 1900; died March 29, aged 78, of chronic endocarditis.

St. Clair, Frank Peter, Salt Lake City; John A. Creighton Medical College, Omaha, 1895; veteran of the Spanish-American War; died March 23, aged 78, of coronary occlusion.

Sargent, Susan Barbara Tallmon, Berkeley, Calif.; Northwestern University Woman's Medical School, Chicago, 1902; died Feb. 21, aged 78.

Scherer, Carl Ahrendt ⊕ Marysville, Calif.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1907; health officer of the Sutter-Yuba Bi County Health Unit; formerly health officer of St. Louis County, Minn., and director of rural health unit No. 4 of the Minnesota State Board of Health; died Feb. 12, aged 69, of common duct obstruction.

Scruggs, Elroy, Paris, Tenn.; Vanderbilt University School of Medicine, Nashville, 1913; member of the American Medical Association; chairman of the board of directors of the Federal Savings and Loan Association; died March 17, aged 71, of coronary occlusion.

Sisk, Clarence Frank ⊕ Zanesville, Ohio; Ohio State University College of Medicine, Columbus, 1926; past vice president and president of the Muskingum County Academy of Medicine; president of the county board of health; died Feb. 22, aged 50.

Smith, Edward Needham ⊕ Oklahoma City; born in Creston, Wash., Oct. 18, 1902; University of Pennsylvania School of Medicine, Philadelphia, 1927; clinical professor of obstetrics at the University of Oklahoma School of Medicine; specialist certified by the American Board of Obstetrics and Gynecology; member of the Central Association of Obstetricians and Gynecologists; obstetric consultant, Oklahoma State Department of Health; affiliated with Wesley, Mercy and University hospitals; died Feb. 26, aged 48, of coronary disease.

Smith, Wallace P., Waupun, Wis.; Northwestern University Medical School, Chicago, 1893; died in Beaver Dam recently, aged 82, of diabetes mellitus and arteriosclerosis.

Spencer, Clay, St. Joseph, Mo.; St. Louis University School of Medicine, 1903; died in the State Hospital No. 2 Feb. 19, aged 71, of cerebral hemorrhage.

Syfert, Alva Clyde, Arkansas City, Kan.; University of Kansas School of Medicine, Kansas City, 1915; died Feb. 15, aged 64, of chronic lymphatic leukemia.

Tetrick, Paul Wyckoff, Mason, Ohio; Medical College of Ohio, Cincinnati, 1904; member of the American Medical Association; on the courtesy staff of the Fort Hamilton Hospital and Mercy Hospital in Hamilton, where he died March 11, aged 70, of cholelithiasis and myocarditis.

Tindall, Herbert Frederick, Pasadena, Calif.; College of Medical Evangelists, Loma Linda and Los Angeles, 1924; certified by the National Board of Medical Examiners; died March 27, aged 52, of bronchopneumonia and generalized lymphosarcoma.

Tyson, Robert Stafford, Frederick, Md.; Hahnemann Medical College and Hospital of Philadelphia, 1902; member of the American Medical Association; on the staff of the Frederick Memorial Hospital; died in the University Hospital, Baltimore, March 23, aged 73, of pneumonia.

Wade, Charles Ernest, Santa Maria, Calif.; University of Oregon Medical School, Portland, 1897; died in Santa Barbara March 5, aged 81, of heart disease.

Walsh, Ford Cooper, Kansas City, Mo.; State University of Iowa College of Medicine, Iowa City, 1894; served during World War I; died in the Veterans Administration Center, Leavenworth, Kan., March 29, aged 78, of carcinoma of the prostate.

Wendt, Charles Isaac, Pittsburgh; Hahnemann Medical College and Hospital of Philadelphia, 1895; served during World War I; on the staff of the Shadyside Hospital; died March 5, aged 79, of arteriosclerotic heart disease.

Wiencke, Edward John ⊕ Schenectady, N. Y.; Albany (N. Y.) Medical College, 1896; member of the American Trudeau Society; past president of the Schenectady County Medical Society; formerly tuberculosis clinician in the health department; served during World War I; past president and member of the board of Glenridge Sanatorium; honorary staff member of the Ellis and St. Clare's hospitals; died March 4, aged 76, of lobar pneumonia.

Wood, Howard J., Rockville Centre, N. Y.; Albany Medical College, 1885; died March 31, aged 89, of arteriosclerosis and uremia.

Yarbrough, Henry L., Tunica, Miss.; Memphis (Tenn.) Hospital Medical College, 1894; died Jan. 7, aged 86.

Young, Edmond Brooks, Vardaman, Miss.; University of Nashville (Tenn.) Medical Department, 1906; member of the American Medical Association; died in the Houston (Miss.) Hospital March 13, aged 68, of heart disease.

Zugg, Clarence Logan, Arkansas City, Kan.; College of Physicians and Surgeons, Medical Department of the Kansas City University, 1902; University of Kansas School of Medicine, Kansas City, 1912; member of the American Medical Association; on the staffs of St. Margaret's and Bethany hospitals in Kansas City; died in the Memorial Hospital, Arkansas City, March 9, aged 76, of myocardial infarction.

GOVERNMENT SERVICES

SELECTIVE SERVICE SYSTEM

OPERATIONS BULLETIN NO. 30

ISSUED: APRIL 9, 1951

AS AMENDED: MAY 16, 1951

SUBJECT: **Special Registrants Completing Internships or Residencies in June 1951**

1. A doctor of medicine or dentistry can perform his service in the armed forces with the least inconvenience to himself and with the least dislocation of medical programs in communities and hospitals immediately following the end of his period of internship or residency. Most internships and residencies are terminated on or about the 30th of June of each year.

2. It is the policy of the Department of Defense not to call to active duty an officer of the Medical Corps Reserve, except in the case of a bona fide volunteer, unless the Medical Advisory Committee concerned certifies that he is currently available for military service. Therefore, the Office of the Surgeon General of the Army has informed this Headquarters that the Army is declining to offer commissions to special registrants unless the registrant has been classified in Class I-A or Class I-A-O and the State Director of Selective Service verifies the fact that the registrant's file contains information submitted by the Medical Advisory Committee concerned indicating that the registrant is considered to be currently available for military service.

3. After a special registrant applies for a commission some time is required to complete his processing. Normally, orders placing reserve officers on active duty must be obtained at least thirty (30) days prior to the date of entry upon active duty. In order that a special registrant who desires to enter military service immediately after completion of his internship or residency training may be in a position to do so without loss of time while awaiting the completion of his processing for a commission and receipt of orders to active duty, local boards are requested to take the following actions:

(a) Those special registrant physicians in the first priority now serving internships or residencies in hospitals who are in Class I-A or Class I-A-O should be advised by the local boards to apply for a commission at the earliest possible date unless they have already done so by answering Item 30 of DD Form No. 390 in the affirmative.

(b) Each special registrant physician in the first priority who is now deferred to complete his internship or residency and whose file contains information submitted by the Medical Advisory Committee concerned recommending that the registrant be considered available for military service on or about June 30, 1951, and who the local board expects to reclassify in Class I-A or Class I-A-O should be promptly so reclassified. If the registrant has not been physically examined and found acceptable within the previous 180 days, the local board shall forward him to the armed forces joint examining and induction station for physical examination and determination of acceptability. As soon as the registrant has been reclassified, the local board should advise the Commanding General of the appropriate Continental Army through the State Director of Selective Service that the registrant is in Class I-A or Class I-A-O and that his file contains the recommendation of the Medical Advisory Committee that he be considered available for service.

(c) Those special registrant physicians in the first priority who have answered Item 30 of DD Form No. 390 in the negative and who have been examined and found acceptable and those registrants who were offered commissions and declined them should each now be offered an opportunity to apply for a commission by signing the following application addressed to the Commanding General of the appropriate Continental Army:

> "I do hereby now apply for a commission in the Medical Corps Reserve of one of the Armed Forces of the United States."

This statement should be signed by the registrant in the presence of a witness and should be delivered to his local board. If the registrant has answered Item 30 of DD Form No. 390 in the negative, the local board should attach to the application for commission Standard Form 89, the original and one copy of Standard Form 88, and the original and one copy of DD Form No. 390 pertaining to the subject registrant. All of these documents should be forwarded to the Commanding General of the appropriate Continental Army through the State Director of Selective Service. If the registrant was offered a commission and declined it, the application for commission without other papers, should be forwarded to the appropriate Commanding General through the State Director.

(d) Each special registrant physician in the first priority classified as available for service who applies for a reserve commission and who either has not been physically examined or was so examined more than 180 days previous to such application should, without delay, be forwarded for physical examination in accordance with the provisions of Part 1650 of the Selective Service Regulations.

ARMY

The Order of the Boar.—The 24th annual dinner of the parent chapter of the Order of the Boar will be held June 9 at the Medical Field Service School, Brooke Army Medical Center, Fort Sam Houston, Texas. The Order of the Boar originated in 1928 at the Medical Field Service School when it was at Carlisle Barracks, Pa., and now has about 2,500 members. Active branches of the organization are located also at Walter Reed Army Hospital, Washington, D. C., Camp McCoy, Wis., and Chicago, Ill. Membership in the Order is limited to officers of the armed services, both regular and reserve, who are interested in preventive medicine.

Outbreak of Gastro-Enteritis.—The Division of Preventive Medicine, Office of the Surgeon General, reports that in an outbreak of acute gastro-enteritis at Fort Meade, Md., on May 17, a total of 389 men were sick enough to report to the dispensary, and 10 are known to have become ill on a bus after leaving the post. Of these men, 102 were hospitalized. Epidemiological evidence indicates that the vehicle of infection was corned beef hash. The incubation period varied from one to six hours. A Staphylococcus was isolated from vomitus, but this organism has not yet been incriminated as a toxin producer. None of the hash was available for laboratory examination.

Awards and Commendations.—The Silver Star was recently awarded to Capt. Robert T. Jensen, Minneapolis. The citation reads in part as follows:

"Capt. Robert T. Jensen, Medical Corps, Seventh Infantry, Third Infantry Division, United States Army. During the night of Nov. 28-29, 1950, near Sackangni, Korea, a battalion of the Seventh Infantry was under strong attack from an estimated two enemy regiments. Captain Jensen, battalion surgeon, heedless of his own safety, continued medical attention to the wounded although enemy artillery, mortar, and small arms fire necessitated placing his aid station and most of its personnel underground. In the morning he called for helicopter evacuation of a wounded man. The enemy directed concentration of fire on the helicopter, but Captain Jensen unhesitatingly accompanied the patient across open ground and supervised loading the wounded man into the helicopter. Captain Jensen's gallantry and devotion to duty reflect great credit on himself and the military service."

Captain Jensen graduated from the University of Minnesota School of Medicine in 1948.

FOREIGN LETTERS

ITALY

Gastroduodenal Ulcer and Work.—Professors Torraca, Palmieri and Rodino reported on "Gastroduodenal Ulcer and Work." Professor Torraca pointed out that duodenal ulcer occurs more frequently than gastric ulcer and there is a higher incidence of the disease among men than among women. In addition to the patient's occupation, mental and physical fatigue, irregular meals, and nutritional deficiency must be taken into consideration. Surgical treatment may consist in pyloroduodenoantral resection, in some palliative operations when resection cannot be performed, or in resection of the gastric fundus according to Connell, devascularization of the stomach according to Hey, and bilateral vagotomy. Torraca obtained excellent results with gastric resection in 506 cases of gastric and duodenal ulcers and in 42 cases of anastomotic ulcer.

Professor Rodino discussed the late results of operations for gastroduodenal ulcer. In a follow-up of patients in whom gastrojejunostomy was performed at the surgical clinic of the University of Naples, he observed 43% complete recoveries, while in 57% of the cases various disturbances were still present. A control examination made more recently showed that cases of complete recovery have increased to 66%. The late results obtained with gastric resection are generally excellent, with completely favorable outcome in 75% of the cases and good results in 22%. There has been complete return to normal of the working capacity in 88% of the cases and partial return in 12% of the patients who underwent gastrojejunostomy, while in the cases in which resection was performed, there was complete recovery in 91.75% and partial recovery in 8.25%. There was complete recovery in 58% of the patients doing heavy manual work, while complete recovery occurred in 78% of patients performing lighter work.

Professor Palmieri discussed the relation between gastroduodenal ulcer and work. When gastroduodenal ulcer is considered as an accident occurring during work, it is necessary to keep in mind the topographic and chronologic criteria, the qualitative and quantitative efficiency of the moment in which it is presumed that the accident occurred, and the clinical history of the patient. The diagnosis should be definite, differentiating ulcer caused by superficial laceration of the mucosa from hemorrhagic gastritis. The evaluation of the injury caused by the accident varies according to the general condition, the type of work, the operability, and the complications. Whether gastroduodenal ulcer may be considered as a professional disease, *caused by lead or mercury poisoning, is a subject of controversy.*

In some cases, the ulcer is considered as an occupational disease, especially when it is due to prolonged standing, to excitement or to inadequate diet. Statistical data are controversial, however. With respect to the criteria of injury entitling the victim to disability pension, it is necessary that existing symptoms, the general condition, the kind of work, and the operability be evaluated.

Deficient Diet.—Nutritional deficiency was discussed by Professors Sotgiu and Panzini. Professor Sotgiu stressed the physiological concepts for appraisal of minimal and excellent nutrition; he divided the deficiencies according to etiogenetic factors, such as poverty and gastrointestinal disturbances, according to etiology in its true sense, i. e., total or partial deficiency of proteins, fats or vitamins, and according to the clinical aspects.

Deficiencies in workers may or may not be related to their work. A generic syndrome of malnutrition or special syndromes that comprise essentially the deficiencies of vitamins and minerals may exist. The generic syndrome prevails in workers.

Professor Panzini discussed the importance of nutritional deficiency, stressing especially the stage in which the undernourished subject, although not having acquired yet a definite disease, is no longer in good health. Besides emaciation and muscular changes, a nervous factor may exist, with increased chronaxia and mental changes. Edema and osteopathy are frequent; the skin and the endocrine glands manifest changes; a hypoglycemic syndrome is frequent. Company-paid lunches may aid in the prevention of nutritional deficiency through qualitative and quantitative caloric intake.

Pathology of the Choledochus and of the Ampulla of Vater.—At the medical academy Filippo Pacini of Pistoja, Professor Salotti of the University of Siena presented a report on a biliary syndrome due to pathologic changes in the choledochus and the ampulla of Vater, approaching this subject from the roentgenologic point of view. Recent preoperative and postoperative cholangiographic observations have revealed pathologic pictures which explain certain biliary syndromes and prompt the consideration of the importance of the area of the ampulla of Vater as a clinical anatomic complex.

Anatomically the region comprises the duodenal papilla, the transversal and longitudinal folds and the ampulla of Vater, the antrums of the bile duct and of the pancreatic duct. It also comprises a small opening through which the common bile duct reaches the papilla running obliquely and with a reduced caliber within the duodenal wall, where muscular bands form the sphincter of the choledochus, while another group of muscular bands surrounds the choledochus and the pancreatic duct, constituting what is properly called the sphincter of Oddi. The sphincter of Balli has a function antagonistic to that of the sphincter of Oddi, namely, that of opening the papillary orifice. Sometimes anatomic and anatomicoroentgenologic changes of the area take place, which concern the varied structures of the papilla and the various ways the bile ducts empty.

Recently Rocchi, Professor Salotti's pupil, demonstrated on the duodenum of cadavers the difficulty of obtaining the picture of the ampulla of Vater and the duodenal papilla as may be observed in living persons. This has led to the conclusion that, in the determination of certain pictures, the functional component occasionally assumes even greater importance than the anatomic one. Choledochographies with rapid serialograms show the various functional phases of the antrum of the choledochus, the spincter of Oddi, and of the duodenum in full synergy.

Work and Diabetes.—This subject was presented by Professors Vesce, Di Prisco and Pisani. Professor Vesce discussed the *etiopathogenesis* of diabetes in relation to work, pointing out that, in the development of diabetes, the factor of work should be considered not only as an exclusive expression of muscular and cerebral activity but also as a summation of physiological, mental and hygienic factors linked with the worker's task. The environment and the working materials are also of importance. Professor Vesce believes that work increases the blood sugar level in severe diabetes, but not all authors share this opinion. Carbohydrate diet is of great importance. Insulin in general increases the hypoglycemia already induced by work in patients with mild diabetes.

Professor Di Prisco discussed employment of diabetic patients. The diabetic patient may become incapacitated by clinical complications, which are more frequent in certain professions, i. e., ocular complications in patients engaged in visual work; vascular complications in businessmen, shoemakers, and farmers; cutaneous sequelae in waiters, brick layers, and farmers, and nervous complications in railroad employees and goldsmiths. It is necessary that workers be examined for diabetes in order that adequate treatment may be instituted early.

Professor Pisani spoke of the relations between diabetes and trauma, pointing out that, while traumatic diabetes is rare, hyperglycemia and glycosuria may be observed after trauma of whatever kind and site. The speaker affirmed that, in order to define the occasional relation between diabetes and trauma, one must demonstrate that the diabetic syndrome did not exist before the

---

The items in these letters are contributed by regular correspondents in the various foreign countries.

trauma occurred; one must be aware of the lesions derived from trauma which may have involved the glycoregulatory system, and must ascertain whether it is real diabetes or extrainsular simple glycosuria and hyperglycemia.

Congress on Occupational Medicine.—The 16th national Congress on Occupational Medicine was held in Naples under the chairmanship of Professor Castellino. Before the congress started, Professor Grasso-Biondi lectured on "Distant Effects in Occupational Pathology," dealing especially with effects of trauma. He discussed the cases in which the discontinuity between the primary and the secondary focus of the lesions is only an apparent one, and how the connection occurs through the vessels, by means of either the blood elements or the central nervous system.

SWITZERLAND

Swiss Antituberculosis Association.—Progress in the treatment of pulmonary tuberculosis has been so important, in recent years, that the Swiss Antituberculosis Association chose as the main subject of its 1951 meeting (31st scientific meeting, Berne, April 13-14), a program aimed to make clear what has improved the treatment of this disease. One of the most interesting subjects was the treatment of the tuberculous cavity of the lung by the method of Dr. G. Maurer (Davos). In his lecture, Dr. Maurer projected a film to show the delicate details of the nonsurgical speleotomy and better to acquaint the group with a method that aroused great enthusiasm as well as criticism. An animated discussion followed this lecture. It seems that the nonsurgical speleotomy is an interesting way of curing the tuberculous cavity, but it has very limitated indications. The difficult technique of this method and the minutiae of a treatment which must last for several months are obstacles to the general use of nonsurgical speleotomy. It seems, also, that in most cases a thoracoplasty must eventually be performed to maintain good results. G. Maurer himself, as well as Prof. J. Hein (who represented the German Society of Tuberculosis), Dr. Good, Dr. de Ridder (Bruxelles), and Prof. W. Catel (Mammolshöhe) believe, however, that the method can be used on a wider scale and often without complementary thoracoplasty. On the other hand, Drs. Arnold (Leysin), Rubin (Davos), Tanner (Arosa), Gruninger (Lucerne) and Mordasini (Berne) think that nonsurgical speleotomy can be used only in exceptional cases and that its results are rather uncertain. Mordasini prefers even the endocavitary drying up according to Monaldi, which permits easier closing of the bronchus. This is also the opinion of Prof. Omodei Zorini, head of the Forlanini Institute of Rome. The main objection to Dr. Maurer's method is that the closing of the bronchus is rarely attained, despite all the techniques used, and the healing of a cavity of the lung is secured only when the bronchus is really closed.

The meeting of Saturday, April 14, was devoted to different communications. Drs. Wissler and Widmer (Davos) talked on the prognosis of pulmonary tuberculosis with cavities in children at puberty. The mortality rate, in open pulmonary tuberculosis, at this age, is no higher than in adults, contrary to general opinion. In the realm of therapeutics, Drs. Staubli and Regli (Montana) stated that paraaminosalicylic acid, given intravenously, drop by drop, can, in high dosage, have an action like that of streptomycin. This meeting was honored by the presence of Professor di Paola, from Rome, who had the same day demonstrated his technique of thoracoplasty in the Inselspital of Berne.

Prof. Henry Sigerist.—Henry E. Sigerist, celebrated his 60th birthday on April 7, 1951. As professor and head of the Institute of the History of Medicine of the famous Johns Hopkins University, he taught this branch to several generations of students. Prof. Sigerist is the author of numerous publications; In Zurich, he founded, in conjunction with G. A. Wehrli, the *Zürcher medizingeschichtliche Abhandlungen;* in Baltimore, he started the *Bulletin of the History of Medicine.* A few years ago, Professor Sigerist left Baltimore for the idyllic village of Pura (Ticino), where he pursues, in his library of over 10,000 volumes, the writing of his "History of Medicine," which will be published in eight volumes, the first of which has just been published.

TURKEY

Vaccinal Encephalomyelitis.—Ord. Prof. Ihsan Hilmi Alantar of Istanbul University children's department and his associate, Dr. Metine Bilger, reported an increase in postvaccinal encephalomyelitis. There were nine cases within three months; two occurred after mumps, three after influenza, two after measles, one after whooping cough and one after smallpox vaccination; two patients died. Four patients were 6, 12, 14 and 17 months old, respectively, and five were 3 to 12 years old. Though the associated infection varied, there was an obvious similarity in clinical and laboratory findings. In a 14 month old patient, a temperature of 42 C. (107.6 F.) developed 10 days after smallpox vaccination. She was admitted to the hospital in coma, having had convulsions for the previous 10 hours. The eyes had rolled upward; reflexes were brisk, and there was no stiffness of the neck. Spinal puncture produced a clear liquor. The Pandy test was positive, and microscopic examination revealed 36 lymphocytes per field. The patient died three hours later.

A 17 month old patient had influenza and angina for a month prior to admission. The fever persisted. During the week before admission vomiting occurred, movement in the right arm and leg was impaired, and the patient became comatose. On admission the patient had a temperature of 38 C. (100.4 F.); the pulse rate was 120; the right reflexes were brisk, and the left reflexes were normal. Corneal reflexes were absent, the Babinski sign was present on both sides. Spinal puncture yielded a clear fluid. The result of the Pandy test was positive, and microscopic examination revealed 32 lymphocytes per field. Cultures were negative. For four days the patient had three to four convulsions, each lasting five minutes. The patient died on the fourth day. The other seven patients recovered in one week to 35 days.

Brucellosis Diagnostic Standard Agglutination.—Sait Bilal Golem, D.V.M., secretary general of the Ankara Refik Saydam Institute of Hygiene, has published his investigations of brucellosis made at the institute. With the antigen obtained from the Department of Agriculture Veterinary Institute at Weybridge, England, experiments have been made at the Refik Saydam Institute of Hygiene and at the Ankara-Etlik Veterinary Biologic Institute with Professor Stableforth's standard serum, with the Refik Saydam institute rabbit serum, and with the Ankara-Etlik institute dry serum. It was found that the Weybridge Institute, the Refik Saydam Institute, and the Ankara-Etlik Institute antigens corresponded but the Stableforth antigen was less agglutinable.

Placental Graft in Eye Diseases.—Dr. Nuri Fehmi Ayberk, chief of the ophthalmology department of the Haidar Pasha Model Hospital-Istanbul, reports good results obtained in eye diseases with placental grafts, a method of therapy first used by Filatoff (Russia) in 1946. Of the 24 patients (14 women and 10 men, 16 to 83 years old) four patients had retinal detachment, three had chronic glaucoma, four had retinitis pigmentosa and 13 patients had different types of neuroretinopathy. In some patients, grafts the size of a pea were placed under the upper conjunctiva, and in some patients this technic was supplemented with placenta extract injections. The placenta, which had been aseptically removed by cesarean operation, was kept at —2 C. for five to six days; the graft was removed from the center of the placenta. The grafts were repeated two or three times after an interval of two months. In the patients with retinitis pigmentosa, the graft improved central vision 1 to 1.5; adaptation to darkness slightly improved a week after the graft. In patients that had been followed for several months, continued good results were obtained. In patients with neuroretinopathy the results were also good. In younger patients and in patients with inflammatory conditions the results obtained were twice as good as in older patients and in those with conditions of degenerative origin. The graft had no beneficial effect on patients with optic atrophy of long duration. In several cases of retinal detachment, the results obtained with the placental graft were so satisfactory that an operation became unnecessary and there was further improvement after the second graft. In patients with chronic glaucoma, the graft did not result in marked improvement; however, in one of these patients, front and side vision was attained.

According to Filatoff the distintegration substances, rather than the hormone and vitamin content of the placenta, produce the stimulating effect on the physiological functions.

BRAZIL

Priority for BCG Vaccination.—Antituberculosis work in Brazil started in 1941, and the National Campaign Against Tuberculosis was founded in 1946. This campaign has a modern, scientific aspect, and it has made a new division of zones of the country. This campaign has started working toward an increase in the number of beds, and the number has grown significantly. At the same time the campaign has been trying to spread the application of BCG vaccination, and there has been an increase in the distribution from 125,000 vials in 1945 to 571,637 in 1949. During the present administration the number of beds for tuberculous patients has been raised from 2,844 in 1944 to 7,153 in 1950 in the state of São Paulo. The expense of medical assistance and hospitals in the state of São Paulo and in the entire country suggests that other more up to date methods, such as BCG vaccination, should be used in the fight against tuberculosis.

In June 1950, there were 375,329 persons vaccinated with BCG in São Paulo. The exceptional conditions in this state, due to a large number of institutions, make it possible to carry out BCG vaccination on a large scale and to enforce Federal Law 484, which requires a certificate of this vaccination in various periods of the life of citizens.

Drs. Nogueira Martins and Pedral Sampaio, of the Liga Paulista contra la Tuberculose, suggest that priority be given to BCG vaccination, among the measures to be carried out in countries that have conditions similar to those of Brazil. Their experience over a period of 15 years with a large number of observations confirmed radiologically and clinically shows favorable results obtained with BCG vaccination in children who live in contagious areas.

MISCELLANY

THE NATIONAL CANCER INSTITUTE

Prepared by George F. Connery of the A. M. A. Washington Office

The National Cancer Institute clearly is one of the world's great centers for research on neoplastic disease.

It is one of seven organizations grouped together at Bethesda, Md. as the National Institutes of Health, but its influence extends to every state and to several foreign countries. Congress has rapidly increased the institute's annual appropriation to the point where it now totals approximately 40 times the average appropriation for the first seven years of the institute's existence. The current total budget of the National Cancer Institute is just over $20,000,000. Only about $4,650,000 is being spent for administration, publications, research, demonstrations and consultations. All the rest goes out in grants: to states for cancer control, to institutions for research and construction of facilities and to individuals to finance specialized training.

The National Cancer Institute was created by Congress in 1937. It has set for itself two major goals: ". . . first, to increase basic knowledge of cancer and, second, to increase the application of our present knowledge of how to prevent cancer deaths." Effort is directed four ways: (1) research in the institute's own laboratories, (2) grants to stimulate and support cancer research in other institutions and by individual scientists, (3) studies and demonstrations in the public health phases of cancer control and (4) training grants to medical and dental schools for undergraduate instruction. Dr. John R. Heller is the director. Responsibilities are divided among three branches and a technical services department, or administrative clearing house.

The Research Branch, supervised by Dr. Heller in the absence of a scientific director, is NCI's own laboratory, where scientists carry on scores of projects aimed at learning more about cancer. At the same time the Research Branch supplements and stimulates the work of private individuals and organizations whose cancer projects are financed by NCI grants. The Research Branch covers a wide range. The research sections, and their operations, as described by NCI are as follows:

The Epidemiology Section (Dr. Alexander G. Gilliam, chief) investigates influences which may be associated with presence or absence of cancer in humans. Case histories of a large number of women with breast and cervical cancer currently are being analyzed, along with controls, to determine whether the two groups differ in any significant respect. A similar study is being made of the relationship between lung cancer and such factors as occupation and smoking.

The Chemotherapy Section (Dr. Murray J. Shear, chief) prepares and investigates chemical substances of possible value in treating human cancer. As a preliminary, screening of about 3,000 drugs and compounds was completed in 1950; about 150 were found to damage test tumors in mice. Clinical research is under way with alpha-peltatin and beta-peltatin, two compounds discovered by this section's scientists in a plant extract.

The Endocrinology Section (Dr. Roy Hertz, chief) investigates the role of hormones in cancer causation, of vitamins in stimulating effect of hormones and in use of hormones and antivitamin substances in treating cancer. A water-soluble form of female sex hormone has been developed; this can be injected directly into the blood stream, making possible much higher blood levels of hormone in breast and prostatic cancer patients than previously attainable. In addition, observations on the favorable effects of progesterone in cervical cancer have offered a therapeutic lead.

The Biochemistry Section (Dr. Jesse P. Greenstein, chief) investigates chemical differences between normal and cancer tissue, looking toward new approaches to therapy. Projects include comparative metabolism enzyme studies; comparison of proteins, fats and other tissue components common to normal and malignant states, and studies of metabolism and nutrition of normal and cancer tissues, using isotopes as tracers. This section worked out techniques for mass-producing all essential amino acids for intravenous feeding. Applying this process, several commercial firms now are preparing to market amino acids at greatly reduced prices.

The Biophysics Section (Dr. Egon Lorenz, chief) studies biologic effects of penetrating radiations, as a means of inducing cancer and as a form of treatment. One important finding is that systematic effects seem to play a significant role in radiation treatment of a transplanted mouse lymphosarcoma. Irradiation of the tumor alone has little effect, but when the whole body is irradiated with the same dose as given to the tumor alone a profound regression of the tumor is noted. Also, it was learned that when the spleen is protected by a lead shield, the whole body irradiation dose could approximately be doubled, with the result that the transplanted tumor did not recur in about 70 per cent of the animals.

The Pathology Section (Dr. Harold L. Stewart, chief) explores and evaluates the transformation in cells and tissues as cancer develops and becomes established. Various tumors similar to those in man are induced in experimental animals by chemical carcinogens, and the histopathogenesis of these tumors is studied during all stages of development. Current interest is focused on eliciting and defining the earliest neoplastic changes and in correlating them with those occurring in human beings. For example, the development of induced carcinoma of the cervix in mice and spontaneous cervical cancer in women are being followed by cervical smears and the processes compared.

The Biology Section (Dr. Howard B. Andervont, chief) studies the problems of growth, differentiation and cell physiology by means of tissue culture, transparent chambers in mice and other techniques. Researchers have demonstrated that the thymus gland is implicated in mouse leukemia, probably as a bridge between the leukemia stimulus and the disease. In certain strains of mice, total removal of the thymus prevented leukemia in most of the animals.

A total of 377 persons are employed in the research branch, which for the current year will spend $3,537,000, all to further NCI's own projects, none going for grants. Opportunities for this branch will be greatly increased with completion, probably in 1952, of the Clinical Center at Bethesda, where 125 beds will be reserved for selected cancer patients.

The Grants and Fellowships Branch, with Dr. R. G. Meader as chief, handles grants to nonfederal institutions and individuals for support of research and of research facilities and training. These grants total almost $9,000,000 this year, but more than half is earmarked for payments on construction projects authorized by Congress over the past three years to increase clinical and laboratory space and equipment for cancer research. There is no money this year for new construction grants. The $16,303,000 previously authorized has been allocated to 47 hospitals, medical schools and cancer research institutions in 27 states and the District of Columbia.

Research supported by the grants program covers most of the wide area of investigation dealing with the causation of tumors, with their growth and dependence on or independence of the rest of the body and with special attempts to develop better diagnostic and therapeutic methods. The function of the branch is to stimulate cancer research and to disseminate knowledge about it. Close liaison is maintained with the American Cancer Society and all other agencies that make grants to support cancer research. Although there are no legal or governmental ties between ACS and the institute, a constant exchange of information insures correlation of government and private programs. The society's board usually contains an official of the institute, and ACS representatives in turn are brought in as institute consultants.

Cancer research funds, like all those awarded for research by the Public Health Service, are not distributed geographically or by population. As an example, institutions in one state (New York) in 1950 received $579,632, or 20.4 per cent of the research grant money appropriated that year, whereas another (Oregon) received only $5,400, or 0.2 per cent of the total.

According to NCI, these figures reflect the situation in each state. Oregon has only one research application, and it was granted in full. New Yorkers asked for considerably more, but not all was granted. The number and dollar value of research grants is said to be in fairly close proportion to the total requested, from state to state, and to the research potential of a region.

In general, the policy has been to support work in recognized cancer research centers where prompt productivity can be expected, while the long range effort is to plant as much money as possible in other areas where it might kindle interest in cancer work, particularly fundamental research.

Through the Cancer Control Branch (Dr. R. F. Kaiser, chief) NCI maintains contact with states, assisting their cancer control activities with demonstrations, consultations and educational programs as well as grants. In amount of grant money distributed ($7,000,000 this year), the Control Branch is second only to the Research Grants Branch. Its staff numbers about 50. The largest single item in its budget is the $3,200,000 set aside for use of states in their campaigns to detect and control cancer. Under the law, the maximum a state health department may receive is established by the population-income-cancer incidence formula, which makes more money available per capita to relatively poor states. The same two states, New York and Oregon, which were used as examples of uneven distribution of cancer research funds are examples of what happens when cancer control funds are passed out. New York's population is about 10 times that of Oregon, yet it received 100 times as much money for cancer research grants. But for control work, New York got only eight and one-half times as much money as Oregon, which meant that the federal government actually was spending more money per capita to help control cancer in Oregon than it was in New York.

Cancer control is the most important program over which the National Advisory Cancer Council does not have jurisdiction. Allocation is made by the staff and director of the Control Branch, on recommendations by a 10 member Cancer Control Committee, established administratively. Represented on the committee are state health departments, medical schools, the American Cancer Society, the American College of Surgeons and other organizations.

Dr. Noka B. Hon, head of the State Aid Section, emphasized that every effort is made to have the physician become the "key man in every situation where federal cancer control funds are expended." Dr. Hon noted that every cancer control program aided by federal funds must have the prior approval of the local medical society, and that patients may be hospitalized for not to exceed three days, and for diagnostic purposes only.

Operating under the Control Branch is a section devoted to studies in environmental and occupational cancer—one area where demonstrable progress has been made. Dr. W. C. Hueper is chief of the Cancergenic Studies Section Control Branch.

Also a part of the Control Branch, under the direction of Dr. J. E. Dunn, is the effort to develop satisfactory cancer diagnostic tests, whose purpose is the detection of possible cancer in mass groups of the public. In work on diagnostic tests and environmental and occupational cancer, NCI's scientists cooperate with state officials, with nongovernment organizations and with researchers who are individually pursuing projects related to these fields. This branch also distributes grants to medical and dental schools to stimulate and coordinate the teaching of cancer control and detection and to stimulate interest in research methods. This year $2,040,000 is being spent on this program, with 78 of the country's 79 medical schools participating. Four-year schools get $25,000, two-year schools $5,000. The Cancer Council passes on these. A total of about $2,000,000 is being spent by the Control Branch this year on these additional programs: demonstrations and consultations, $275,000 (the Cancer Control Committee advises on this program, but neither it nor the Council passed on individual projects), and special projects (recommended by the Advisory Council) $929,000; clinical traineeships for physicians, $372,000 (physician gets $10 a day, must spend at least half time on cancer work; Council establishes policies, but screening is done by staff groups).

The general public, and particularly the medical profession, are represented in management of National Cancer Institute through the National Advisory Cancer Council. By law the council is authorized to review research projects or programs and to recommend prosecution of those it considers promising; to collect information on cancer research going on anywhere, by personal investigation if necessary; to review applications for research grants; to recommend acceptance of conditional gifts to the NCI, and in general to advise the Surgeon General of PHS on all operations of NCI.

The council now is composed of 15 members, with the Surgeon General as chairman. Until recently membership was nine, with the six appointed members "leading medical or scientific authorities . . . outstanding in the study, diagnosis or treatment of cancer." The chief medical officer of Veterans Administration and a medical officer designated by the Secretary of Defense also serve on the council as ex-officio members, making, with the Surgeon General, a total of 15 members. The four-year appointments are made by the Surgeon General, with approval of the Administrator of the Federal Security Agency. The Surgeon General can act only on the recommendation of the council on (*a*) research grants, (*b*) grants to medical and dental schools, (*c*) special projects and (*d*) construction grants. The council is not authorized to act in fellowship or clinical traineeship grants or grants to states under the control program.

The council meets three times a year. Prior to the meetings, applications are screened by study sections, made up of experts in the particular field, primarily nongovernmental but generally including representatives of the Veterans Administration, the Public Health Service and usually one of the military services. Study sections are concerned with the scientific merits of a particular project, rather than its importance relative to competing projects. However, the sections place a priority on each application. It is the duty of study groups to assemble all essential information for the benefit of the council, visiting the applicant if necessary to round out their information. Assisting each study group is an executive secretary (a trained PHS scientist). Generally, according to Dr. Meader, the study group has its report in the hands of each member of the council about one month before council meetings.

The council determines its own method of procedure as well as the length of its meetings. Dr. Meader said the council approves about 60 per cent of the applications. He also noted an increasing tendency for the study groups and the council to apply the same criteria. They disagree now on about one grant in 10; they formerly diagreed on one in four.

Records show that in only one case has the Surgeon General rejected a project approved by the council. Later information showed that other government funds were supporting a similar project. This close agreement is brought about through advance staff work and the fact that the Surgeon General, who has final veto power, participates in council deliberations.

BUREAU OF LEGAL MEDICINE AND LEGISLATION

MEDICOLEGAL ABSTRACTS

Governmental Hospital: Liability to Pay Patient for Agent's Negligent Acts.—The plaintiff sued for damages for personal injuries resulting from the alleged negligence of the defendant hospital while she was a paying patient therein. From a trial court ruling in favor of the defendant, the plaintiff appealed to the Supreme Court of Appeals of West Virginia.

The defendant hospital was created by a 1943 statute authorizing the County Court of Monongalia County to establish, equip and maintain a hospital to be known as Monongalia General Hospital. The controlling question, said the Supreme Court of Appeals, is whether the defendant hospital is a public corporation and is engaged in the performance of a governmental function. The plaintiff contended that in the operation of the hospital, under the statute, and in accepting and treating her as a patient for hire, the defendant was not engaged in the discharge of a governmental function, but acted in a proprietary capacity and is liable for the damages caused by the negligence of its agents and employees. The defendant hospital insisted that it is a public corporation, that in the operation of the hospital it was engaged in the performance of a governmental function, and that it is immune from liability for the negligence of its officers, agents and employees.

It is obvious, said the court, that the defendant is a public corporation. Its trustees were incorporated and the hospital was established by the statute. The title to the hospital property, by the terms of the statute, is vested in the County Court of Monongalia County, which holds the property of the county, a political subdivision of the State, for the benefit of the county or its citizens and inhabitants, in trust for public purposes. Furthermore, continued the court, the contention of the plaintiff, that the operation of the hospital by the defendant, when she, a paying patient, was injured, was for profit and in a proprietary capacity instead of in the performance of a governmental function, is not well founded. Neither the public character of the defendant nor the nature of its operation was changed or affected by the payment of dues or charges for the treatment which the plaintiff received as a patient. Numerous decisions of the appellate courts of other jurisdictions so hold and in a prior West Virginia case the Supreme Court of Appeals said: "The fact that one is a paying patient does not alter the [general] rule. Such patient is the recipient of the donors' gratuity only in a lesser degree than one who makes no payment. The hospital building, with its equipment, management, and its great possibilities for the alleviation of suffering, was provided by charity. In using the organization made possible and supported by that charity, a paying patient, to that extent, benefits by the charity."

Continuing, the Supreme Court of Appeals said that the basic test in determining whether a public corporation, in its operations, is engaged in the discharge of a governmental function or is acting in a propriety capacity is whether the act performed is for the common benefit of the public or is for the special benefit or profit of the corporation. It is clear beyond question, the court concluded, that the operation and the maintenance of its hospital by the defendant are for the common benefit of the public generally and are not for the special benefit or the private gain or profit of the defendant, the trustee, or the County Court of Monongalia County.

In cases involving liability of a hospital for the negligence of its officers and agents, the character of the particular institution, whether it is public, charitable, or private, is important for the reason that legal principles which apply to a public hospital are different from those applicable to a hospital operated and maintained for private gain or profit. A former West Virginia case, in recognizing the distinction between a private hospital and a public hospital with respect to such liability, used this language: "The policy of the law forbids liability of a state or municipal hospital for negligence of its servants and physicians; it being a governmental agency." The plaintiff insists, however, that the language of the statute which charges that the defendant hospital board shall be a corporation and may sue and be sued, authorizes this action. The argument is not persuasive. The provision that a corporation may sue and be sued does not create a cause of action or impose liability for its negligence or confer upon a person injured by such negligence the right to maintain an action for damages against it. The authority conferred upon a public corporation by statute to sue and be sued does not render it liability for acts for which no liability is imposed by law. Accordingly the judgment in favor of the defendant hospital was affirmed.—*Shaffer v. Monongalia General Hospital, 62 S.E. (2d) 795 (West Virginia 1950).*

MEDICAL MOTION PICTURES

The Male Sex Hormone: 16 mm., color, sound, showing time 22 minutes. Produced by Sturgis-Grant Productions, Inc., 314 East 46th St., New York 17. Sponsored by and procurable on loan from Schering Corporation, 2 Broad St., Bloomfield, N. J.

This motion picture begins with a brief exposition of the historical interest in the subject and leads up to our present day knowledge of anatomy and physiology of the male genital organs. The relation of the pituitary gonadotropin, LH or ICSH, and the production of testosterone is shown by animation; a brief section on steroid chemistry is also given. The physiologic effects of the use and the lack of testosterone are discussed. Types of hypogonadism in early and late years are shown with pictures of certain cases seen in the clinic. A typical course of testosterone therapy in a 15 year old boy is described in detail, and the patient's progress is followed. The fact that androgen therapy is assuming importance in the field of gynecology is mentioned, and certain important metabolic effects following testosterone administration are briefly discussed.

The film introduces two controversial subjects. The first occurs in the discussion of the use of the hormone in the treatment of the male. The Council on Pharmacy and Chemistry does not recognize testosterone for treatment of the male climacteric, nor is the use of the hormone recognized for the treatment of circulatory symptoms. In the film, the use of testosterone is advocated for dysmenorrhea; this also is not recognized. All other indications mentioned are acceptable and the film itself is an excellent presentation of the physiologic background for the production of the male sex hormone and of its effect. However, the use of the trocar for the introduction of pellets is not universally accepted, since bleeding may occur in the area of insertion of the trocar and prevent absorption of the pellets. Therefore, many prefer the purely surgical approach of making an incision, stopping all bleeding, inserting the pellets and closure by surgical methods.

Although this film may be of general interest to the medical profession, it cannot be entirely recommended in its present form. The photography and narration are very good.

POSTGRADUATE CONTINUATION COURSES FOR PHYSICIANS

Compiled by the Council on Medical Education and Hospitals for the Period July 1, 1951 to Jan. 15, 1952

---

1. $5.00 for all of the courses.

2. Tentative course.

3. Plus $10.00 laboratory fee.

4. Physicians may apply to National Foundation for Infantile Paralysis for financial assistance to attend course.

5. Residents. Non-residents $225.00 plus incidental fees of about $50.00 for both residents and non-residents.

6. Free to residents of radiology.

7. For members of medical society and A. M. A. $50.00 to non-members.

8. Iowa State Pediatric Society members. Non-members $10.00. Sponsored by Iowa State Pediatric Society in conjunction with U-Iowa.

9. Surgery $910.00.

10. For 1 month, $250.00 for 3 months, $450.00 for 6 months, $650.00 for 9 months and $850.00 for 12 months.

11. Attendance encouraged from Regular, Reserve and National Guard medical officers on active duty with the Armed Forces; Reserve and National Guard medical officers, with the Armed Forces, not on active duty, at no expense to the government, and civilians, at no expense to the government.

12. Attendance limited to Regular, Reserve and National Guard Army medical officers and Regular, Reserve and National Guard Air Force medical officers on active duty. 25 spaces available at each hospital.

13. Attendance limited to Regular, Reserve and National Guard medical officers on active duty with the Army, Navy and Air Force; and civilians on a space available basis, limited to 8 spaces in each class.

14. [illegible] be to [illegible] listed [illegible] one month prior to the opening date of the course:

(a) Applications from Army Medical Officers on active duty only, will be forwarded to the Office of the Surgeon General, Attention: Personnel Division, Career Management Branch.

(b) Army Medical Officers not on active duty and civilian physicians should be forwarded through channels to the Commander of the installation offering the course. Applications will be approved on a space available basis.

(c) Personnel from other federal agencies. Applications should be made through channels as appropriately announced by each agency.

15. Stated 2 week period may be followed by additional studies at $100 per week. Course also may be taken by Philadelphia area physicians on 6 consecutive Thursdays, 36 hours, at $150.00.

16. In addition to tuition fee indicated there is a *$5.00 registration* fee which covers all courses taken within a 12 month period.

17. Course may be taken 1 to 12 months. Tuition prorated accordingly.

18. Course may be taken 3-12 months. Tuition prorated accordingly.

19. For those who find it desirable to spend a shorter period of time than 1 year, arrangements may be made to take this course from 1 to 9 months if facilities permit. Derm. and Syph. 2.

20. For physicians residing outside of Cleveland, $20.00 for those residing in Cleveland, interns no charge.

21. 1st year. $100.00 each successive year.

22. Special training courses in V. D., Mental Hygiene, M and C Health, Hospitals Administration and Medical Care Administration.

23. Of the Medical Society of the County of Kings and State University College of Medicine at N. Y. C.

24. Kansas Medical Society and Kansas State Board of Health also sponsoring.

25. Menninger Foundation, Winter Veterans Administration Hospital, Topeka State Hospital and Kansas State Board of Health and Kansas Medical Society sponsoring.

26. New Jersey State Dept. of Health also sponsors.

27. Also 20 senior Surgical Residents.

28. Or any 4 weeks, $125.00 each week.

29. Designed to meet the requirements for certification by the American Board.

30. For Specialists.

31. Or an equivalent period on a part time basis.

32. [illegible] higan Department of [illegible] Michigan Medical Sch[illegible] College of Medicine.

33. Co-sponsorship of Washington State Medical Ass'n. and Washington Dept. of Health.

34. Sponsored by American Psychoanalytic Ass'n., New York.

35. Advanced Candidates in training only.

36. *Open only* to Physicians who have been formally approved and accepted for training by the Admissions Committee of the Philadelphia Psychoanalytic Institute.

37. Bingham Associates Fund, Contributing agencies.

38. There may be available fellowship endowment stipends for bona-fide pathology residents. There has been in the past and may be possible in the future.

39. Also sponsored by Oklahoma State Dept. of Health.

40. In cooperation with National Foundation for Infantile Paralysis.

41. In cooperation with Division of Tuberculosis, Bureau of State Services, USPHS.

42. No charge for room and board.

43. 4 weeks $110.00, 1 month $200.00 and 2 months $300.00.

44. Under special circumstances student may begin on a date other than September 17 and may be admitted for a period of 6 to 12 months.

45. Sponsored by Northeastern section of the American Urological Ass'n., Buffalo, N. Y.

46. Sponsored by Los Angeles Urological Society, L. A.

47. Sponsored by USPHS and Arkansas State Board of Health.

48. Course given by Hahnemann Medical College, Dept. of Cardiology, Philadelphia.

49. Co-sponsored by San Francisco Dept. of Public Health.

MEDICAL LITERATURE ABSTRACTS

AMERICAN

A.M.A. Am. J. Diseases Child., Chicago

81:313-464 (March) 1951

- *Familial Leukemia: Report of Leukemia in Five Siblings, with Brief Review of Genetic Aspects of this Disease. R. C. Anderson.—p. 313.
- Adrenal Cortex Extract in Pediatrics: Possible Effect on Respiratory System of Newborn. R. W. Provenzano, P. McGovern, R. Schultz and J. Hester.—p. 323.
- Prevention of Minor Skin Irritation (Miliaria) and Impetigo in Newborn. J. Glaser, M. L. Thompson and T. D. Benson.—p. 329.
- *Adverse Mercurial Reactions in Form of Acrodynia and Related Conditions. J. Warkany and D. M. Hubbard.—p. 335.
- Cleidocranial Dysostosis Syndrome: Report of Case in Negro Child Exhibiting Retarded Growth. R. B. Scott and L. O. Banks.—p. 394.
- Dermatomyositis with Nephritis in Negro Child. J. E. Bradley, M. E. Drake and H. P. Mack.—p. 403.
- Mixed Tumor of Liver: Report of Case with Review of Literature. D. H. Milman and D. M. Grayzel.—p. 408.

Familial Leukemia.—A family is reported on in which five of eight siblings have had leukemia in early childhood. Except for a leukemoid reaction in another sibling, no other blood disorders, and only one case of cancer, are known among the 135 near and distant relatives. A brief review is made of the literature dealing with hereditary factors in leukemia. It appears that a genetic factor is often involved, but definite conclusions regarding the mode of inheritance would be premature. Workers generally favor the idea of a low penetrance dominant gene, but such a family as the one reported on in this paper would suggest instead a rare recessive gene with high penetrance. It may well be that in leukemia, as in many other diseases, the mode of inheritance varies in different families, owing to differences in the predisposing genes themselves. There have been 39 previous reports in the literature on the occurrence of multiple cases of leukemia within a single family but this is the first reported family with leukemia in more than three siblings. Videbaek found that 8.1% of 209 leukemic patients had relatives with leukemia.

Mercurials and Acrodynia.—Warkany and Hubbard suggest that exposure of hypersensitive children to mercury is the most important factor in the causation of infantile acrodynia. Exposure to mercury was demonstrated in 38 of 41 acrodynic children by the presence of the metal in their urine. In 23 of these children mild mercurous chloride (calomel), teething powders or anthelmintic tablets containing mild mercurous chloride, ammoniated mercury ointment and mercury bichloride used for rinsing diapers were ascertained to be the sources of mercury. Idiosyncrasy to mercury that manifests itself in acrodynia exists particularly in infants and small children, while older children and adults have a higher tolerance. There are undoubtedly other factors that lower tolerance, but they are unknown at present. Acrodynia is only one of the forms in which hypersensitivity to mercury can manifest itself. Acrodynia has some but not all the recognized manifestations of mercury poisoning. Transitional states between acrodynia and various established forms of mercury poisoning exist. It is possible that metals, drugs and toxic substances other than mercury produce disease pictures resembling acrodynia. The effectiveness of dimercaprol (BAL) in the treatment of acrodynia could not be clearly demonstrated in the series of cases described. It is possible that in cases of long standing the effect is not so striking as in cases of acute mercury poisoning.

Dermatitis and Leukoderma Due to Rubber Gloves.—For patients with so-called "housewife's" eczema of the hands, dermatologists frequently recommend the use of cotton or fabric-lined rubber gloves for household chores. A recent experience suggests that this recommendation carries with it added risks. A housewife complained of an extremely pruritic dermatitis. It was learned that she had used bluettes® gloves in her household tasks. Patch tests were performed with portions of smooth blue rubber of the outer surface and the rubberized fabric of the inner surface. Results of the tests were positive. The dermatitis responded slowly to treatment. When the woman resumed her household tasks she wore cotton gloves under golden glo® (natural latex) gloves. This was followed by a flare-up. Dryness and superficial scaling of the hands were evident. Blotchy areas of erythema appeared on the face a few hours before the patient's admission to the hospital. On the second day she manifested a generalized pruritic, erythematous, urticarial rash and became extremely disturbed emotionally, to the point of requiring restraints. The patient was treated for varying periods with oral diphenhydramine hydrochloride, doxylamine (decapryn®) succinate, chloral hydrate, codeine, meperidine (demerol®) hydrochloride, colloidal and coal tar solution baths, wet dressings with aluminum acetate solution in 1 to 15 dilution, 1% salicylic acid in petrolatum and one fever treatment with intravenously administered typhoid vaccine. It was concluded that the patient had a contact dermatitis and dermatitis medicamentosa and that diphenhydramine hydrochloride was responsible for the emotional disturbance. Later, scattered areas of leukoderma developed at the sites where the dermatitis had been severest and at the sites of the patch tests. Six months later, repigmentation was noticeable. It was found that one of the bluettes® contained monobenzyl ether hydroquinone, which is the only compound used in the manufacture of rubber articles that has been reported to produce transitory leukoderma.

The Association library lends periodicals to members of the Association and to individual subscribers in Continental United States and Canada for a period of five days. Three journals may be borrowed at a time. Periodicals are available from 1940 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied with stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted.

Late Effects of Cerebral Birth Injury.—Over half of 419 children who had mental retardation, convulsive disorders, and cerebral palsy, singly or in combination, had a history suggestive of birth injury, while in about one of six cases the difficulty could be traced to postnatal injury. In only one out of six did the findings suggest a hereditary or congenital defect as the cause of neurological difficulty. Excluding cases of severe idiocy, 172 cases of probable birth injury were studied by pneumoencephalography, electroencephalography, and psychometric examination. Premature separation of the placenta, placenta previa, kernicterus, prematurity, oversized infant, toxemia, and maternal illness are listed as probable causative and contributory factors in the prenatal period, whereas "heavy" anesthesia and sedation, prolonged labor, the use of oxytocics, breech delivery, cesarean section, cord defects (prolapse, tightening about the neck, or holding back the head), the use of high forceps, and precipitous delivery are the probable causative factors at the time of birth. Sedation and heavy anesthesia appeared as possible causes of 17% of birth injuries. Second in prominence was a story of the head being held back by the nurse or intern until the physician arrived. This is a common practice. Cortical atrophy revealed in pneumoencephalograms is accepted as presumptive evidence that the brain was injured following complete formation. This finding, together with changes attributable to organic disease in the electroencephalographic tracings, was present in almost all patients with a known history of birth injury and in an unsuspectedly large number of other children in whom the history was obscure. Decreased cerebral blood flow was present in cases in whom gliosis might have followed cerebral injury. Behavior disorders in children without retardation, spasticity, or convulsions appear to be possible sequelae of milder degrees of cerebral injury at birth.

Role of Adrenal Cortex in Peritoneal, Pleural, and Pericardial Effusions.—Moehlig and Steinbach present a hypothesis to explain certain peritoneal, pleural, and pericardial effusions, which are found in Meigs' syndrome of ovarian fibroma, some cases of severe hypothyroidism, intestinal lipodystrophy (Whipple's disease), and Addison's disease. This hypothesis assumes that adrenal cortical deficiency is present in all of these syndromes and that this in turn produces disturbances of the serosal layer in these diseases. Embryologic relationships suggest why the adrenal cortex influences the development and function of the mesothelium, and it is already known that the adrenal cortex influences the development and function of other mesodermal structures, namely, the epithelium of most of the urogenital organs, and the striated muscles, both skeletal and cardiac. As evidence in support of their hypothesis the authors cite the following observations. A case of severe hypothyroidism with tremendous ascites and hydrothorax cleared up completely with the administration of adequate dosage of thyroid substance. Since patients with untreated myxedema show an inadequate adrenal cortex response to pituitary adrenocorticotropic hormone (ACTH), the possibility arises that there was adrenal cortical insufficiency in this case and that the administration of desiccated thyroid restored the capacity of the adrenal to respond to endogenous pituitary adrenocorticotropic hormone. This in turn may have corrected the mesothelial disturbance. In Whipple's intestinal dystrophy too there are sometimes signs of increased pigmentation of the skin and hypotension suggestive of functional impairment of the adrenal cortex. The involvement of the mesothelial serous layers then could be due to changes in the electrolyte and water metabolism. The possible relationship of the adrenal cortex to intestinal absorption has been the subject of speculation in both Whipple's disease and sprue, and some patients with Addison's disease have steatorrhea as well as ascites, hydrothorax, and pericardial effusion.

Extreme Hyperglobulinemia in Hepatic Necrosis.—A man, aged 36, was hospitalized because of jaundice of three weeks' duration. No other symptoms were present, and the past medical history shed no light on the present illness. A soft, rounded, slightly tender liver edge was felt 3 cm. below the right costal margin. Laboratory tests disclosed extreme hyperglobulinemia and definite hypocholesterolemia. Electrophoretic patterns of the serum revealed that the elevation of globulin was due almost entirely to the gamma globulin level. The highest value of gamma globulin previously reported was approximately 4 gm. per 100 cc. In the reported case the gamma globulin level was 7.31 gm. per 100 cc. For about eight weeks the symptoms changed little, but then there was a turn for the worse and death followed nine days later. The anatomic diagnosis was subacute hepatic necrosis with cirrhosis. Whenever extreme hyperglobulinemia has been described in liver disease, it has been associated with subacute hepatic necrosis or postnecrotic cirrhosis, on a presumed infectious or toxic basis. Whereas no case of Laënnec's cirrhosis has been observed with serum globulin values above 6.12 gm. per 100 cc., four patients with postnecrotic cirrhosis have been described, in addition to the case described above, as having total protein values above 11 gm. per 100 cc., or a globulin value above 8 gm. per 100 cc., or both. It is suggested that marked hyperglobulinemia represents a mounting production of antiliver protein antibody that continues to cause necrosis of the liver. Judging by the few cases in which it has been seen, extreme hyperglobulinemia in liver disease indicates an unfavorable prognosis.

Treatment of Primary Syphilis.—Of 360 patients with primary syphilis reported on, 268 were treated with penicillin and 92 with penicillin plus neoarsphenamine (mapharsen®) and bismuth. All the patients completed a minimum of six months of regular monthly follow-up. The median age of incidence was 24 years. The sex ratio was 85 male patients to 15 female patients. There was a febrile Herxheimer reaction in 281 patients. Not the presence, the height, or the absence of a febrile Herxheimer reaction was valuable for prediction of success or failure of treatment. In general the seronegative and low titer seropositive (earlier) primary syphilis patients had a better chance of successful treatment than those with high titers (later). In general the height of the serologic titer at the time of treatment was directly proportional to the length of time required to attain seronegativity, but there were many exceptions to this generalization, as shown in one patient with a titer of 1: 128 who took 24 months to achieve seronegativity. Early diagnosis, preferably by dark field test, is indispensable for good results. One week of penicillin therapy totaling up to 4,800,000 units proved to be not enough for primary syphilis. In the author's experience penicillin plus neoarsphenamine and bismuth has proven somewhat more efficacious than penicillin alone, the penicillin in each instance being confined to one week of therapy and the bismuth and neoarsphenamine, when added, requiring eight additional weekly treatments.

Bilateral Cortical Necrosis of Kidneys.—The occurrence of bilateral cortical necrosis of the kidneys is reported in a woman aged 29, seven months pregnant, and in an infant with diarrhea and circulatory failure. Both patients died, and necropsy was performed. Both cases demonstrated the greater sensitivity of the outer zones of the renal cortex to the lesion of cortical necrosis. There was focal necrosis in the zone immediately adjacent to the medulla in both cases, and consequently the juxtamedullary zone was not completely spared. In the case of the woman necrosis of the blood vessels was revealed only within the necrotic areas, and no classic thrombosis was seen. The glomeruli within the necrotic areas were distinctly congested. This distention of glomerular capillaries by red blood cells precluded the primary occurrence of thrombosis within preglomerular arteries. These observations are in keeping with those cited in the literature. The pathogenesis of bilateral (symmetrical) cortical necrosis of the kidneys is controversial. The condition is considered to result from ischemia, but various concepts of the cause of the ischemia have been advanced. Cortical necrosis was induced in rabbits by the injection of staphylococcic toxin into a peripheral vein and directly into the renal artery. Two major morphological changes, marked glomerular and postglomerular congestion, suggesting stasis, and cortical necrosis were noted. No thromboses or arterial necrosis outside the necrotic areas were observed. The thesis of Dunn and Montgomery, which considers cessation of glomerular blood flow as the cause of the ischemia, appears to be supported by these observations. It is suggested that the toxin causing damage to the glomerular membrane thereby effects a rapid escape of plasma fluid into the tubule and that postglomerular capillary stasis also may play a part in the mechanism of ischemia. The immediate cause of the glomerular damage was not elucidated in the authors' experiments. Although cortical necrosis was produced readily, the same technique did not yield lower nephron nephrosis. These observations justify caution in ascribing varying intensities of the same mechanism as operating in the pathogenesis of the two lesions.

Neurofibromatosis and Related Lesions.—A case of generalized neurofibromatosis is described in which a malignant growth and spinal curvature were present in addition to the skin lesions. According to the hypothesis advanced in this paper, it is not neurofibromatosis as such that is inherited but a predisposition to the disease, a predisposition that is thought to influence the development of a great variety of lesions at the basic intrinsic factor level, a less varied group of lesions at the neural intrinsic factor level and a still more restricted group of lesions at the neurofibromatosis level. Lesions representative of all three levels may be present in the same person, and, as these lesions may lead to secondary ones, it may prove difficult to discover the etiology. Bone lesions, like spinal curvature, congenital pseudarthrosis of the tibia and small size of certain individual bones, are thought to be related to neurofibromatosis at the basic intrinsic factor level. It is suggested that intrinsic factors may play a part in the etiology of a variety of conditions that occur in patients or their close relatives who, though free from neurofibromas, have one or more lesions belonging to the neurofibromatosis complex, namely, neurilemmoma, meningioma, fibroma, lipoma, angioma, tumors of the glioma group in the brain or cord, tumors of the optic nerve, glial hyperplasia, epilepsy, cutaneous pigmented patches, spinal curvature, congenital pseudarthrosis of the tibia, small size of bones, hydrocephalus and spina bifida.

Hirschsprung's Disease.—Megacolon has been divided into Hirschsprung's disease proper and idiopathic megacolon. The second group is much the commoner, and here megacolon results from chronic constipation. Hirschsprung's disease proper is a congenital malformation, only microscopically demonstrable. Pathologically it is an agenesis of intramural ganglion cells and dysplasia of autonomic nerve bundles. Its functional manifestation is lack of coordinated peristalsis in the affected segment, leading secondarily to an active type of megacolon in the bowel proximal to this. The demonstration by barium enema of undilated or narrow bowel distal to the megacolon is diagnostic. Resection of the inert distal bowel by rectosigmoidectomy is now considered the rational treatment of Hirschsprung's disease. A total of 40 consecutive cases of Hirschsprung's disease (37 in boys) are the basis of this report. A genetic study of the disease was made in the families of 37 of these children. The evidence supports a genetic determination of the disease. The over-all chances of a male sibling of a patient with a known case being affected are about 1 in 5; those of a female sibling being effected are small. Of 37 patients who were treated by rectosigmoidectomy, three died during or after operation and in two others the operation has been very recent. The other 32 children are all in excellent condition. Half of them require no laxatives, and only three complain of occasional abdominal distention. Pathologic studies uniformly revealed the expected picture in the terminal undilated segment of bowel. A review of published reports shows that the length of the involved segment varies significantly. In over 90% of the reported cases there are pathologic changes in the rectum and part or all of the sigmoid colon. Less than 10% of patients have extremely long abnormal segments that appear to be incompatible with life if untreated.

Penicillin Sensitivity in Staphylococci.—In the past three years several bacteriological laboratories have reported an increasing incidence of penicillin-resistant strains of Staphylococcus pyogenes, and some writers have concluded that the clinical value of penicillin is steadily diminishing. It seemed worth while, therefore, to see whether a clear-cut distinction could be established between penicillin-sensitive and penicillin-resistant strains of staphylococci, and, if so, whether this distinction was reflected in the clinical manifestations of infections caused by these organisms. The material for the inquiry was collected between November 1948 and May 1950 from practitioners and from three hospitals. The great majority of the patients from whom the material was obtained had previously received penicillin treatment. There was a clear bacteriological distinction between penicillin-sensitive and penicillin-resistant staphylococci. All sensitive strains were of the same order of sensitivity as the Oxford Staphylococcus, and all the resistant strains produced penicillinase. The two types of staphylococci were in the main associated with different types of lesions—the penicillin-sensitive strains with acute and closed or deep-seated infections, whether acute or chronic, the resistant strains with superficial lesions. The penicillin-resistant staphylococci were significantly less often associated with signs of inflammation or suppuration than the sensitive strains. In view of the different types of lesion with which they were associated, this result cannot be interpreted as indicating that the resistant strains were less virulent than the sensitive, but the difference in the inflammatory signs associated with the two types of infection may help to bring into perspective the clinical importance of the reports of an increasing incidence of penicillin-resistant staphylococci.

Changes in Blood After Operations.—Studies on the effects of surgical operations on nitrogen and electrolyte metabolisms revealed that immediately after operation the urinary excretion of nitrogen and potassium was increased, whereas that of sodium and chloride was decreased. This appeared to be a fundamental part of the body's response to injury and to be independent of the type of surgical operation; it was not abolished by dietary measures. Studies on 30 persons, including four healthy controls, were made to ascertain whether corresponding changes took place in the blood. Changes in the composition and volume of the blood after radical surgical operations followed a general pattern, which was independent of the type of operation or the method of postoperative feeding. In all the patients there was a sudden fall in the plasma protein level, in particular the albumin concentration. In most cases the globulin concentration gradually rose to values well above the preoperative levels. Increases in amount of nonprotein (urea) nitrogen were observed in some patients. Hemoconcentration on the day after operation, followed by hemodilution, was observed in all patients. Changes in hematrocrit values were accompanied by corresponding changes in red blood cell count. An immediate reduction in total blood chloride, with an inconstant reduction in plasma chloride, was followed in most patients by a rise in total blood chloride. There were corresponding changes in the serum sodium. There

An asterisk (*) before a title indicates that the article is abstracted. Single case reports and trials of new drugs are usually omitted.

was some evidence that electrolyte ions were transferred from the plasma to the red blood cells. On the day after operation there was a significant reduction in plasma and blood volume and in the total amounts of proteins and sodium circulating in the plasma. The measurements of the "thiocyanate space," an attempt to determine the volume of extracellular fluid, were not entirely satisfactory. The small changes in the concentrations of the blood constituents indicate the efficiency of differential renal function in assisting the production of the inflammatory exudate; they emphasize the true biological function of the blood as a vehicle.

The "Trap" Headache.—In an attempt to discover the cause of his own headaches, Bostock first investigated errors of refraction, but the purchase of glasses with various corrections for his astigmatism had only fleeting effects on the headaches. The septic focus theory and the gastrointoxication theory were then investigated, but neither tonsillectomy nor purgatives had more than a temporary success. Then it was suggested to him that the chief cause is repressed hate. Repressed hate is related to conflict. There is a "war in the mind" between the desirable and the obtainable. There is an underlying frustration; the sufferer is in the "trap." He wishes to escape, but the exits are barred. The situation is "hate-full." When this arises the headache appears. The author gives illustrative examples of "trap" headaches and shows that treatment by psychotherapy is highly satisfactory. He believes that the term migraine should be redefined and suggests a new definition. Headache is the registration in consciousness of changes in potential in the regulating mechanism that provides a neural energy constant. Changes in this potential can be due to organic causes. This accounts for the identical nature of the headache in both organic and psychological types.

*Histologic Observations on Icterus Occurring During Treatment with Streptomycin. M. Janbon and L. Bertrand.—p. 510.

Icterus and Streptomycin Therapy.—Needle biopsies of the liver were obtained by anterior thoracic route in seven of 20 cases of icterus occurring during treatment with streptomycin. Microscopic examination of the liver tissue specimens revealed constant periportal infiltration, frequent centrolobular disorganization and a normal aspect of the intermediate liver cell cords except for an increase of pigment and mitosis at the border of the central lesions. These observations suggest that icterus occurring in the course of streptomycin therapy is not related to a toxic action of the antibiotic, but to inoculation hepatitis (homologous serum jaundice), the mechanism and anatomic lesion of which are the same as those of icterus occurring in the course of other methods of treatment in series. The lesions are also the same as those of epidemic hepatitis. Results of biopsy of the liver thus emphasize the infectious nature of homologous serum hepatitis, particularly of the hepatitis observed in the course of streptomycin therapy, and of epidemic hepatitis. Biopsy of the liver thus confirms the experimental findings and epidemiological observations of Havens and of Neefe with respect to inoculation jaundice occurring in the course of other methods of therapy.

Bronchography with Water Soluble Contrast Substance.—Schultz-Møller reports on 47 bronchography series done in the course of about a year with water soluble contrast substance. He states that while this procedure is more elaborate and time consuming than bronchography with iodized oil, and requires a larger personnel, the contrast substance disappears rapidly after the examination and never affects later roentgen examination of the lung. It seems to be less injurious to the lung tissue than iodized oil. The method fails less often than bronchography with iodized oil and gives more certain results.

Linitis Plastica.—Kolpak stresses that the pathogenesis of linitis plastica is not uniform, since inflammatory changes as well as scirrhous carcinoma or carcinoma fibrosum may present the picture of this condition. Thus a diagnosis of linitis plastica does not yet permit a decision as to whether the lesion is benign or malignant. When Brinton coined the term linitis plastica in 1859, he wanted to stress the extraordinary hypertrophy of the submucous connective tissue of the stomach. The author briefly cites the opinions of different authors on linitis plastica and then describes two cases in which the macroscopic aspects of a gastric lesion suggested this condition but in which microscopic examination revealed carcinoma fibrosum (scirrhous carcinoma) in the first patient and colloid (gelatiniform) carcinoma in the second. The author believes that if the surgeon encounters linitis plastica, he should proceed as if the lesion were carcinomatous. Rapidly prepared histologic sections are inadequate for a definite diagnosis. In the course of a thorough histologic study special attention must be given to the marginal portions of the tumor and to the regional lymph nodes, which on superficial inspection may appear normal.

BOOK REVIEWS

The Eye Manifestations of Internal Diseases (Medical Ophthalmology). By I. S. Tassman, M.D., *Associate Professor of Ophthalmology, Graduate School of Medicine, University of Pennsylvania, Philadelphia. Third edition.* Cloth. $12. Pp. 672, with 279 illustrations. C. V. Mosby Company, 3207 Washington Blvd., St. Louis 3, 1951.

This book offers an important contribution to the medical literature because of its systematic exposition of the relation between various general diseases and ocular pathology. It is a valuable reference book for the internist and specialist in other fields, because it clarifies this relation and provides insight into the ophthalmological aspects. To the ophthalmologist it presents a broad view and emphasizes a relation that is all too easy to minimize in such a highly specialized field.

No new chapters have been added to the present edition, but an attempt has been made to bring all material up-to-date. The first five chapters, dealing with basic anatomical and clinical aspects of ophthalmology, will be of interest chiefly to those without previous ophthalmological training. The chapters on congenital and hereditary eye manifestations and on infections and infectious diseases contain much important information for all readers. In the final chapters there is a systematic discussion of the ocular complications of a wide variety of conditions involving all organs and systems. This portion has particular value as a reference source for rare and unusual conditions, some of them occurring so infrequently as to be unfamiliar in their ophthalmological aspects.

The book is well written and well edited and contains adequate illustrations. It is highly recommended to anyone with an interest in the subject.

Florence Nightingale. By Lucy Ridgely Seymer. Cloth. $1.75. Pp. 154, with 9 illustrations. The Macmillan Company, 60 Fifth Ave., New York 11, 1950.

Intimate details of the life and background of this woman whose name has come to be synonymous with nursing are given in a sympathetic and enthusiastic review of her principal activities. As the author points out, Florence Nightingale, who lived to the age of 90, witnessed a period of great social evolution, and she herself was an important factor in the development of some of the new concepts.

After presenting data on the childhood and youth of Florence Nightingale, as well as her preliminary nursing training, the author gives a detailed report on the important part played by the "Heroine of the Crimea" during that two year war. There are two chapters devoted to this, followed by accounts of her services to various commissions and subcommissions studying army nursing and hospital problems, the founding of her nursing school, and her work for India. There is a chapter on the general subject of her writing, and the final chapter describes her last years, in which she was able to abandon somewhat the aloofness that governed many of her earlier years. An appendix lists the principal events in her life; another contains notes on "minding baby," and a third gives the various biographies of this pioneer nurse.

Klinische Haematologie: Ein Grundriss für Studierende und Ärzte. Von Professor Dr. Werner W. Siebert, *Direktor der medizinischen Klinik am städtischen Krankenhaus Moabit, Berlin.* Cloth. 31 marks. Pp. 260, with illustrations. Urban & Schwarzenberg, Thierschstrasse 11, München 22; Meinekestr, 13, Berlin W. 15, 1950.

The book is intended as a basic textbook for students and physicians. It serves only this purpose. The text is sketchy, without thoroughness in background or discussion of controversial materials. The illustrations are poor. There is a good section on definitions, which, in view of the confusion in hematological terminology, is most helpful. The section on methodology is also good and adds to the value of the book. The absence of a bibliography represents a grave deficiency. Unfortunately, the book contributes nothing new to the hematological literature.

An Introduction to the Study of Viruses. By Kenneth M. Smith, F.R.S., *Director of Plant Virus Research Unit, Agricultural Research Council, Molteno Institute, Cambridge.* Cloth. $2.50. Pp. 106, *with 16 plates.* Pitman Publishing Corporation, 2-6 W. 45th St., New York 19; Sir Isaac Pitman & Sons, Ltd., Pitman House, 39-41 Parker St. Kingsway, London, W.C.2, *1950.*

This book reflects the author's attempt to discuss the viruses causing disease in man, animals, and plants in one volume. The book is divided into chapters presenting the history of virology; the modes of spread and arthropod relations of viruses; a brief description of some representative virus diseases, and the isolation, physical and chemical properties, electron microscopy, serology, and control of viral infections.

This small volume is fascinating reading. The author certainly has the faculty of condensing an enormous richness of material into a few pages and presenting it in such a way that medical, veterinary, and plant virologists can equally profit from its reading. The plates contain excellent black-and-white illustrations, mostly microphotographs by Markham and Smith. The last pages of the book consist of a well-selected bibliography.

The Conquest of Malaria. By Dr. Jaime Jaramillo-Arango. Cloth. 21s. Pp. 125, with 36 plates. William Heinemann, Ltd., 99 Great Russell St., London, W.C.1, 1950.

In this small volume, the author attempts to recall the historical struggle against malaria and to record the names of pioneers who have added most important, fundamental contributions to the knowledge and treatment of the disease. It is divided into three parts: the mosquito-malaria theory, a critical review of the basic facts in the history of cinchona, and progress in the knowledge and treatment of malaria. About three-quarters of the book is devoted to the first two parts, which are treated in a comprehensive manner. Antimalarial drugs other than cinchona derivatives are dealt with very sketchily in part 3. Chlorguanide hydrochloride ("paludrine"), which receives major attention in the last part of the book, could be more adequately discussed, and the vast amount of research carried out in the United States during World War II receives most superficial discussion. Practically no mention is made of the importance of insecticides and DDT, which will probably prove of greater value than all therapeutic measures in the ultimate conquest of malaria.

The book is readable but cannot be recommended as a well-balanced monograph on the history of antimalarial therapy.

Florence Nightingale 1820-1910. By Cecil Woodham-Smith. Cloth. $4.50. Pp. 382, with illustrations. McGraw-Hill Book Company, Inc., 330 W. 42d St., New York 18; Aldwych House, Aldwych, London, W.C.2, *1951.*

Cecil Woodham-Smith has developed an unsual story of Florence Nightingale, which goes far beyond any previous biography because of her access to letters and documents never before used in the Nightingale story. The early chapters covering the period of Florence Nightingale's life up to the time of her training as a nurse are really a study in psychiatry. During this period, the conflicts of an ambitious young lady with a family who wanted her to be a social butterfly led her to the verge of a psychosis, which is well described by Mrs. Woodham-Smith.

The description of Florence Nightingale's baptism of fire during her training period and the Crimean War reports in detail physical and administrative conditions that were intolerable. The detailed analysis of the problems at hand and Miss Nightingale's reaction to them makes one feel that one is living with her as part of her inadequate staff.

Shortly after her return to England, Miss Nightingale suffered a physical exhaustion which caused her to be bedridden for most of the rest of her long life. Yet, in spite of this, she accomplished many remarkable things that had never been accomplished by anyone in the best of health. The political manipulation carried on in the government in England, particularly in the War Department and in the Indian Office, was sufficient to break many powerful politicians; yet, working from her bed, Miss Night-

---

The reviews here published have been prepared by competent authorities and do not represent the opinions of any official bodies unless specifically stated.

ingale analyzed the situation so as to direct her work toward reasonably successful conclusions and was able to command the respect of all who worked with her. Her many interests are astonishing and are well set forth in this biography. Not only did she raise nursing to the level of a profession, but she established visiting nursing, improved hospital construction and administration, was deeply concerned with environmental sanitation, rearranged the administration of the entire medical service of the army, and made many contributions to the broad field of social welfare, particularly among the underprivileged classes of England. As so often is the case, her real recognition did not come until she was too old to understand, in spite of the fact that during her entire period of activity she received the continuing appreciation of the soldiers whom she served during the war.

Any physician involved in administrative medicine or concerned with the problems of government as they relate to medicine should read Mrs. Woodham-Smith's "Florence Nightingale 1820-1910." Any physician in an administrative position who feels that he has problems will discover that the problems that he has are insignificant when compared with the administrative problems that Miss Nightingale had throughout the greater portion of her life.

Taschenbuch der inneren Medizin. Von Prof. Dr. Walter Seitz, Direktor der Med. Univ. Poliklinik München. Cloth. 15 marks. Pp. 344, with 15 illustrations. Wissenschaftliche Verlagsgesellschaft m. b. H., Tübinger Strasse 53, Stuttgart-1, 1950.

This little pocketbook measures 5 by 7 inches and is described on the jacket as designed to present the entire knowledge of internal medicine in epitomized form. The contents, in 18 sections, cover diseases of the lungs, pleura, blood vessels, heart, blood-forming organs, upper and lower digestive tract, liver, biliary system, pancreas, kidneys, lower urinary organs, locomotor system, endocrine system, and also diseases due to animal parasites, disorders of metabolism, infectious diseases and the commoner poisons. In addition, there is a table of notifiable infectious diseases, which in the United States, however, varies from state to state, and the incubation period of the infectious diseases is listed in another table.

The descriptions of the various diseases usually follow a fixed order covering their origin, symptomatology, diagnosis, treatment, and prognosis. The attempt to include the entire field of internal medicine in so cramped a space means considerable compression, though the author usually manages to present the important data in clear language. It is true that there are occasional errors and omissions: the malaria of drug addicts, rat bite fever, and ornithosis are not mentioned, nor is heroin and marihuana addiction. These lacunae do not detract from the high informative level of most of the material presented.

The book is well printed on good paper, but the type, though clear, is small. The cloth binding is substantial and attractive. There are a few well-designed diagrammatic illustrations and a good index. No bibliographic references are included. The scope of internal medicine has so widened in the past half century that it is a difficult feat to cover the field completely in such small compass, but a book of this type is doubtless of some value for quick reference or for a rapid review of the subject.

Blood Clotting and Allied Problems: Transactions of the Third Conference, January 23-24, 1950, New York, N. Y. Edited by Joseph E. Flynn. Cloth. $3. Pp. 224, with 52 illustrations. Josiah Macy, Jr. Foundation, 565 Park Ave., New York 21, 1950.

This book contains the verbatim report of the formal and informal discussions of many aspects of blood clotting by the following experts: L. B. Jaques, A. U. Blaustein, I. S. Wright, L. M. Tocantins, C. E. Brambel, F. D. Mann, A. J. Quick, J. E. Flynn, K. M. Brinkhous, J. A. Ferguson, N. W. Barker, J. T. Edsall, J. H. Olwin, R. S. Overman, W. H. Seegers, B. Alexander, J. G. Allen, H. J. Tagnon, G. E. Burke, J. D. Ferry, L. A. Wood, and others.

The discussions are centered specifically around the newer anticoagulants, "danilone" (phenylindanedione [PID]), ethyl biscoumacetate (tromexan® ethyl acetate), and paritol® (a sulfated mannuronic acid); the use of vitamin K in anticoagulant therapy; the mode of action of bishydroxycoumarin (dicumarol®); problems of prothrombin assay, and accessory factors needed for coagulation.

This book contains the latest advances in the field of coagulation, presented and discussed by those who have made these advances. For those interested in blood clotting, this book is highly recommended and even required. For the student and practitioner, it is too technical and academic to be very useful.

Progressive Resistance Exercise: Technic and Medical Application. By Thomas L. DeLorme, B.S., M.D., Assistant in Physical Medicine, Massachusetts General Hospital, Boston, and Arthur L. Watkins, A.B., M.D., Assistant Clinical Professor of Medicine, Harvard Medical School, Boston. Foreword by Joseph S. Barr, M.D. Cloth. $5. Pp. 245, with illustrations. Appleton-Century-Crofts, Inc., 35 W. 32nd St., New York 1, 1951.

Interest in progressive resistance exercise has developed rapidly since Dr. Thomas DeLorme initiated studies concerning this type of exercise at the Gardiner Army General Hospital in Chicago during World War II. Drs. DeLorme and Watkins have now prepared an excellent general textbook describing in careful detail the technic and medical application of this particular type of exercise. As mentioned in Dr. Barr's foreword, the system of exercises described "has a sound physiologic basis and muscles subjected to this type of exercise can be shown to have increased power both to the satisfaction of the patient and the physician."

The book is divided into ten sections: (1) introduction, (2) physiology by Frances A. Hellebrandt, (3) principles, (4) technics, (5) fractures, (6) knees by Francis E. West, (7) hips, (8) neurological conditions, (9) medical conditions, and (10) adolescents by J. Roswell Gallagher.

A common error is to attempt to restore muscular power by endurance-building exercises. Power is best restored when one offers heavy resistance to muscular effort. The authors have devised elaborate apparatus and detailed technics for progressive resistance exercises and then have discussed carefully the indications for the restoration of muscular power by means of these progressive resistance exercises. As pointed out by Dr. Barr, the technics described have been tested by practical clinical use. The volume should be useful to physicians interested in physical medicine, orthopedists, and other physicians who are concerned with problems of muscular rehabilitation, as well as to the therapists who assist such physicians.

Die Tuberkulose: Ihre Erkennung und Behandlung. Von C. Arold, et al. Herausgegeben von Prof. Dr. Hellmuth Deist und Prof. Dr. Hermann Krauss. Cloth. 68 marks. Pp. 754, with 297 illustrations. Ferdinand Enke, Hasenbergsteige 3, Stuttgart, W., 1951.

This textbook has been compiled in the best tradition of the comprehensive German "Handbuch." It deals thoroughly with all aspects of the diagnosis and treatment of tuberculosis. The thirteen chapters include pathology, microbiology, chest, orthopedic, childhood, abdominal, urogenital, skin, eye, ear, and upper respiratory tract tuberculosis, with a special section on the surgical treatment of the pulmonary localizations of this disease. In spite of the differences in the approach of the various coauthors to the subject, tuberculosis is considered throughout the entire book as a generalized disease with local manifestations. On the whole, the concepts of Schroder, Sauerbach, and Brauer are being followed and enlarged. There is a real richness of material and references, especially from Germany. One misses, for example, Western methods of laboratory diagnosis and prevention of tuberculosis. Most of the illustrations are very good, especially the histologic sections. The book has been carefully edited and printed.

Diabetes Guide Book for the Physician. Paper. Gratis. Pp. 79. American Diabetes Association, Inc., 11 W. 42nd St., New York 18, 1950.

This convenient pocket-sized book was prepared by the Committee on Education of the American Diabetic Association. Intended as a guide for physicians, it covers in outline form the commonly accepted procedures of diagnosis and treatment of diabetes mellitus, hypoglycemic reactions, and diabetic coma. The section dealing with the calculation of diabetic diets is particularly instructive. The principle of food exchanges is explained, and a number of sample meal plans are listed. Short lists of references suitable for the physician and for both the patient and the physician have been included. This little manual will undoubtedly live up to its aim, to help the busy medical practitioner give his diabetic patients effective treatment.

QUERIES AND MINOR NOTES

FLUORINE IN PUBLIC WATER SUPPLIES

To the Editor:—*There is much talk about the fluorination of public water systems. I would like to know about the toxicology of such water solutions of fluorine. 1. At what concentration will mottling of the teeth probably occur? 2. At what concentration will general systemic symptoms occur, and what would the symptoms be? 3. What concentration of fluorine in drinking water is necessary to produce death in a human?*

H. Curtis Wood, M.D., Philadelphia.

Answer.—1. Mottling of the teeth will probably occur when the concentration of sodium fluoride is 2 to 5 parts per million (2 to 5 mg. per liter). Smith and Smith (Technical Bulletin, Arizona Agriculture Experimental Station, No. 43, 1932) found that mottling did not occur when the water contained less than 2 ppm. Later, Smith, Lantz and Smith (*J. Am. Dent. A.* 22:817, 1935) found the threshold concentration may be as low as 1 part per million. Lansbury (*M. Clin. North America* 28:1428, 1944) states: "The optimum intake of fluorine is probably about 1 milligram per day or a water supply containing 0.9 parts per million. The amount of fluorine in water sufficient to cause fluorosis (mottled enamel) is 1.7 or more parts per million."

2. Lansbury also states: "Exposed workers may ingest as much as 25 mg. a day which in a year or so results in chronic fluorine poisoning. Chronic fluorine poisoning is characterized primarily by mottling of the enamel of the teeth, osteosclerosis and other miscellaneous findings.

"It is rather generally agreed that toxic symptoms appear with the ingestion of a single dose of from ¼ gram to 1 gram of sodium fluoride, the toxic dose depending on the conditions existing in the individual at the time of ingestion. The symptoms include vomiting, abdominal pains and diarrhea."

3. The fatal dose of sodium fluoride appears to be about 3 to 4 Gm. This again depends on the conditions existing at the time of ingestion. Thienes, (Clinical Toxicology, Philadelphia, Lea & Febiger, 1940, p. 167) states that 0.25 Gm. has caused nausea and 4 Gm. has caused death. Greene (*U. S. Nav. M. Bull.* **43**:551, 1944) states that the fatal dose is between 5 and 10 Gm. This agrees with Lidbeck, Hill and Beeman (*J. A. M. A.* **121**:826 [March 13] 1943), who state: "The symptoms of acute fluorine intoxication include vomiting, abdominal pain, diarrhea, painful spasms and paresis, excessive salivation, perspiration and dyspnea. Death is usually attributable to respiratory paralysis."

INFECTIOUS HEPATITIS IN A SURGEON

To the Editor:—*I recently returned from the Korean war with severe infectious hepatitis, for which I am now being treated. As a surgeon, I wonder what the possibilities are of transmitting this disease to any patient on whom I may operate in the future by such an accident as pricking my finger with a suture needle during an operation. Is it known how long this virus remains in the body after clinical recovery? How long should I wait before I begin operating again?*

Harold F. Hamit, M.D., Fort Sam Houston, Texas.

Answer.—It is difficult to provide an exact answer to this very pertinent question. The period during which viremia persists in epidemic hepatitis is unknown, but the preponderance of evidence seems to indicate that it does not extend into the convalescent period. The experience of Murphy (*Gastroenterology* 5:449 [Dec.] 1945) shows the IH virus is almost certainly present in the blood during the preicteric phase, and it may possibly persist for a short time thereafter. Beyond this point, proof of viremia is lacking.

An authority on the epidemiology of hepatitis has said: "In respect to the question of duration of viremia with virus IH infection, there are no adequate data concerning this point. The few volunteers whose sera were tested late in jaundice and several weeks afterwards proved not to have infectious sera. However, in another group with persistent mild findings for some months, vague phenomena suggesting mild hepatitis occurred in volunteers inoculated with sera, stool and liver biopsy material collected at intervals after the acute attack (*J. Clin. Investigation* 26:329 [March] 1947). From a practical viewpoint, as there is no way of setting a time limit in reference to this question, I would be inclined to advise the patient to ignore this question. One really has no data to say that he would be any less likely to be infectious six months from now than shortly after recovery from the acute attack."

A second authority, to whom this question was referred, replied as follows: "I do not know of any reliable information on the duration of viremia in infectious hepatitis. Virus has been recovered from the feces as long as two months after an acute attack, and there is reason to believe that in certain individuals it may be present for longer periods. I feel confident that in some individuals it may be present in the blood for considerable periods, but this is not documented with any degree of certainty."

In view of the very large number of persons who have had the disease and who have not been restricted in their activities because of it, it would not seem that any limitation should be imposed.

The following references are suggested: Neefe, J. R.: *M. Clin. North America* **30**:1407 (Nov.) 1946. Neefe, J. R., and Stokes, J. Jr.: *J. A. M. A.* **128**:1063 (Aug. 11) 1945. Neefe, J. R., Gellis, S. S., and Stokes, J. Jr.: *Am. J. Med.* **1**:3 (July) 1946.

CLICKING IN THE EARS

To the Editor:—*What causes continuous "clicking" in a patient's ears? The condition has been present for five years and has increased in intensity and is audible to anyone who listens. The clicking simulates clacking castanets and occurs with definite regularity. Inspection of the drums fails to reveal motility. There is no appreciable hearing loss. The eustachian tubes are patent to catheterization and inflation without apparent diminution of the clicking sounds.*

E. S. Hallinger, M.D., Camden, N. J.

Answer.—Adventitious sounds from the ear can come from rhythmic opening of the eustachian tube with an audible sound, from the blood vessels in the form of a bruit or from spasmodic contractions of the intratympanic muscles, that is, the stapedius or tensor tympani. Normally, these muscles contract only reflexly to loud sounds as a protective mechanism against overstimulation of the inner ear. In some persons, involuntary rhythmic contractions of these muscles occur analogous to the tic of the muscles around the eye or elsewhere. There is no local treatment. The use of a mild sedative might be of some help, and reassurance that this is nothing serious is helpful.

ASTHMA IN A COTTON MILL WORKER

To the Editor:—*A 55 year old man has spent 30 years working in a cotton mill. He has suffered from bronchial asthma for 25 years and for the past three years from bronchiectasis. His general health is fairly good. He weighs 190 pounds (86 Kg.). At times his asthmatic condition becomes almost intolerable. I would like information regarding treatment.*

J. L. Powe, M.D., Hartsville, S. C.

Answer.—It does not immediately follow that the conditions described result from exposure in a cotton mill. The conditions mentioned are common, apart from employment. It is well recognized that a pulmonary state termed "byssinosis" or "mill fever" occurs among cotton workers; it is variously regarded as either allergic or resulting from a specific infection. Byssinosis

---

The answers here published have been prepared by competent authorities. They do not, however, represent the opinions of any official bodies unless specifically stated in the reply. Anonymous communications and queries on postal cards cannot be answered. Every letter must contain the writer's name and address, but these will be omitted on request.

in cotton mills is little known in the United States; it is commoner in England. In the uncertainty of the occupational origin of the asthma, it may be well to conduct suitable tests seeking specific causes. The detection of the precise cause, whether cotton, house dust, animal dander or cosmetics, may prove the salient step toward management. Otherwise the treatment for the acute episodes should be symptomatic and as for any other spasmodic asthma. Until recently treatment for bronchiectasis, with or without asthma, has been unpromising. More recently good and prolonged results have been achieved through the use of antibiotics as aerosols. Penicillin so applied irregularly has proved valuable. Streptomycin in conjunction with penicillin may be preferable. Regardless of the cause, treatment should conform to that required for any other bronchial asthma and any idiopathic bronchiectasis.

ANNUAL X-RAY EXAMINATIONS

To the Editor:—*A man in his late forties suffered from pseudo ulcer symptoms and hyperacidity in his younger years. In the last 10 years gastric analyses indicated a slight hyperacidity. Because of recurring complaints and gastric cancer in his father, he has been advised to have yearly x-ray examinations; about 14 such tests have been done. There are no changes of the skin or hair. Is it advisable to continue this procedure in order to detect any probable malignancy at an early stage?* *M.D., Illinois.*

Answer.—Walters, Gray and Priestley (Carcinoma and Other Malignant Lesions of the Stomach, Philadelphia, W. B. Saunders Company, 1942) in reviewing 2,772 operative cases of carcinoma of the stomach, noted a positive family history of malignancy in 20 per cent of the cases. Others have also reported data suggesting that heredity plays a role in carcinoma of the stomach. It is reasonable, therefore, to keep a dyspeptic, in whom a strong family history of carcinoma is elicited, under closer surveillance than average. Such persons should be reasonably protected by yearly examination, unless a significant change of symptoms occurs, in which case more frequent examinations may be necessary.

If the factors of exposure to roentgen rays, both with respect to the roentgenoscopic and the roentgenographic examinations, are kept to a minimum, or within well defined physical limits, an adequate examination of the stomach can be done at yearly intervals or oftener with perfect safety. If these exposure factors are exceeded, there is definite hazard in the excessive irradiation to which the patient is exposed, whether a single or repeated examinations are done.

HOT FLASHES AND ENDOMETRIOSIS

To the Editor:—*A 45 year old patient had a left ovarian cyst removed; her right ovary, also cystic, had been removed 10 years previously. She had multiple endometriomas of the bowel, one of which was subjected to biopsy. She is now having hot flashes. Could small doses of diethylstilbestrol be given to control these with safety, or would the drug in any amount stimulate the remaining endometriomas? The pathologist's report read "functioning" endometrioma. If diethylstilbestrol can be used, in what dosage? If it is not safe to use, what may be substituted?* *M.D., Massachusetts.*

Answer.—There is some disagreement on this subject. Formerly it was thought that any estrogen would stimulate endometriosis and make it progress. More recent studies indicate that in patients who have endometriosis and also have their ovaries or parts of them, large doses of diethylstilbestrol prevent ovulation, and it is thought by some to make the lesions regress. In patients without ovaries, endometriosis is stimulated exactly as is the endometrium, and certainly large doses, or medication given over a long period of time, will make the endometrium function wherever it is located. Most patients in past years were treated with drugs other than estrogens and in most cases were fairly comfortable. Thyroid in small doses is helpful as are any of the mild sedatives, especially used at night or during periods of undue stress. Of most importance is psychotherapy and rearrangement of the patient's habits to avoid friction of one sort or another and to relieve emotional upsets. Male sex hormones can be used, but here care must be used not to overdose and produce masculinization. In isolated instances, if the condition could be controlled in no other way, one could use small doses of diethylstilbestrol, 0.1 or 0.2 mg. daily for short periods of perhaps a week unless pain developed from one of the nodules.

PROGRESSIVE MUSCULAR DYSTROPHY

To the Editor:—*In a family of five children, the oldest boy, now 13, began to get weak in the legs at the age of 5 and finally became weak all over. He now is helpless in a wheel chair. Twins, a boy and a girl, age 5 years, have to catch things to get up when sitting down. The diagnosis is muscular dystrophy or myasthenia gravis. Physicians can offer no encouragement as to recovery. What is the cause of this disease?* *J. P. Powell, M.D., Dalhart, Texas.*

Answer.—The diagnosis here is obviously progressive muscular dystrophy, not myasthenia gravis. Unfortunately there is no known treatment of value for this condition, and it is the natural history of this condition to grow gradually worse. The only recommendation that can be offered is that this family have no more children, as this is definitely a hereditary disease.

CYCLOPROPANE SHOCK

To the Editor:—*In* The Journal *of March 3, 1951 (page 688), the answer to the inquiry on "Cyclopropane Shock" fails to mention a procedure that has been found to prevent or at least minimize this "shock." It was taught by Waters and is mentioned by Dripps in the reference given in the answer. In the last five to 15 minutes of anesthesia the patient is allowed to inhale a gaseous mixture brought increasingly closer to room air in oxygen content and temperature. This is accomplished by use of a semiclosed carbon dioxide absorption technique with a large volume flow of gas. It is most conveniently done with nitrous oxide and oxygen. Starting with a flow of 2 liters per minute each of nitrous oxide and oxygen, one gradually increases the flow of nitrous oxide to 8 liters per minute of nitrous oxide by the end of the operation. The flow of oxygen is maintained at 2 liters per minute. This procedure gradually lowers the concentration of oxygen in the inspired mixture to that in room air, allows for a slow elimination of the carbon dioxide excess built up during anesthesia with a closed carbon dioxide absorption system and decreases the temperature of the inhaled gases toward that of room air.*

PERIODIC ATTACKS OF DIFFUSE ABDOMINAL PAIN AND DIARRHEA

To the Editor:—*In the Feb. 24, 1951 issue of* The Journal *(page 605) aid is sought in explaining recurrent attacks of abdominal pain at weekly intervals for two years. The reply gives a number of probable causes and methods of diagnosis but fails to mention the possibility of periodic abdominalgia. Your columns have been a fertile source of reports of other unusual periodic conditions which I have added to my collection; yet in not one of the replies to queries has the possibility of periodic disease been mentioned. Studies of these conditions have been published twice in* The Journal *(***136:***239 [Jan. 24] 1948,* **141:***175 [Sept. 17] 1949). Some of the more interesting queries with replies may be listed: Obscure Fever in a Child (***141:***958 [Nov. 26] 1949), Recurrent Herpes of Penis (***139:***1303 [April 30] 1949), Pain in Penis and Perineum (***143:***210 [May 13] 1950), Polyarthritis (***139:***192 [Jan. 15] 1948). The query on Familial Periodic Pain (***139:***1123 [April 16] 1949) led to the study of a family in which 23 members had life-long recurrent attacks of arthralgia, the report of which soon will appear in* The Journal. *Evidently recurrent disorders of various kinds occur often in general practice as diagnostic and therapeutic problems.*

THE STATURE OF AMERICAN MEDICINE 1951

PRESIDENT'S ADDRESS

John W. Cline, M.D., San Francisco

The American Medical Association was founded 104 years ago, to improve medical education and elevate the standards of medical care. Throughout its history these have remained its major objectives. Except for a few war years, the Association has held an annual session, and the 100th meeting is now taking place in Atlantic City. The medical welfare of the people of our country is entrusted largely to the medical profession. Current health conditions and medical progress will be reported at this meeting and, by way of the press, radio and other media, will be transmitted to the nation.

It is a great privilege to address my colleagues here assembled, and to speak to the physicians throughout the country and to the American people, concerning the American Medical Association, its aims and objectives.

THE WORLD LOOKS TO AMERICA FOR LEADERSHIP

As history counts the years, the United States is a youthful country and American medicine also is young. Our country and the medical profession and the medical institutions which serve it have reached early maturity. Today, as never before, the world looks to us for guidance and leadership. We are the most favored among nations because the light of liberty burns brightly here. Individual freedom, opportunity and incentive are the cherished birthright of our people. Likewise, we of American medicine are most favored among doctors. We live and work in an atmosphere of individual liberty, and we have the priceless stimulus of academic and scientific freedom. We are strong because we possess the dignity of free men.

ONLY FREE MEN CAN PRESERVE OUR MEDICAL ACHIEVEMENTS

Only if we perpetuate this heritage can we continue to provide the ever improving quality of medical care which is the right of the American people. During the past 2½ years we have been compelled to fight to maintain this essential freedom. The critical struggle to remain a free profession was not of our asking, but was forced upon us by those who have lost faith in traditional American concepts, and by those who hold the welfare of the American people to be less important than their own political advantage.

We undertook to acquaint the people with the facts. They have recognized the hazard to the quality of their medical care and the danger to their freedom inherent in socialized medicine. They have spoken out clearly and emphatically against it. We are grateful for the perception and the unequivocal expression of the American people.

SERVICE TO HUMANITY IS MEDICINE'S PRIME OBJECTIVE

The "Principles of Ethics of the American Medical Association" opens with this statement: "The prime object of the medical profession is to render service to humanity; reward or financial gain is a subordinate consideration."

To every doctor of medicine, let me say that this is a time for searching self-examination and earnest rededication to the high principles of our profession. We hold in trust the medical welfare of the nation, and to that trust we owe not only the conscientious application of our skills but tireless devotion.

To me, this hour marks the high point of my career. It is the beginning of a year of service to the health and medical welfare of our country and to my profession. It is a great honor to become President of the American Medical Association, but I assume that office without false pride. The responsibility not only to American medicine but to the American people is great. I accept it with humility—born of its importance—but face the coming year with confidence based on an intimate knowledge of my profession, and a steadfast belief in its ability and determination to render progressively greater service to our people.

THE THREAT OF CATASTROPHE—ON TWO FRONTS

These are troubled times. The dark clouds of war hang menacingly over us. We must be prepared for catastrophe, should it come. If it does, the responsibilities of medicine will increase many fold. The Association has been working closely with the Department of Defense and other agencies of government in planning for such eventuality.

Simultaneously, we face the possible loss of freedom through the destruction of our constitutional guarantees of liberty and through avarice or moral disintegration in

---

Read before the One Hundredth Annual Session of the American Medical Association, Atlantic City, N. J., June 12, 1951.

high places. As citizens, regardless of our occupations, we must recognize that the right of self-determination—the right to be master of one's own destiny—has disappeared in many countries. It is threatened in others, including our own. The independence of the individual, his freedom of speech and his right to follow the trade or profession of his choice are basic issues. Only those who now enjoy such advantages can preserve them.

THE AMERICAN PEOPLE WILL RESPOND

I have a deep and abiding faith in the intelligence and integrity of the American people. They will respond as they did when their medical welfare and their medical freedom were threatened. We accepted the challenge of the would-be socializers not only because of the threat to our own professional freedom but on behalf of the welfare and freedom that is the right of all Americans. The members of the American Medical Association are more vigilantly alert than ever to their duties as citizens and will oppose socialistic schemes which would jeopardize the freedom of any segment of our society.

Primarily, we are physicians and our first obligation is to protect and preserve the health and medical welfare of the American people. A number of factors influence these important aspects of life, but medical care is one of the foremost. It is, therefore, appropriate at this time for American medicine to render a report of its stewardship.

AMERICAN MEDICINE ASSUMES WORLD LEADERSHIP

American medicine has gone steadily forward. Some of the once great medical systems of the Old World have faltered and declined under stultifying government control while American medicine has forged into a position of world leadership.

The greatness of any nation can be measured, in part, by the health of its people. The United States *is* great and has developed the *foremost* medical care in the world. You are all beneficiaries, but you are contributors to this system as well.

American medicine could not have attained its present position without the assistance and cooperation of our educational institutions, our scientists, our colleagues in public health, our hospitals, nurses, dentists, labor and management, and all the American people, working with initiative and independence toward the same goal. Together we have made great progress in the fight against death and disease, until today we are the healthiest large nation in the world.

TWENTY ADDED YEARS OF LIFE

Since the turn of the century, almost 20 years have been added to the life span of the American people. The general death rate during the same period has been cut almost in half. This represents the saving of more than one million American lives every year. Our population has doubled since 1900, but the population 65 years of age and older has quadrupled. This results from saving the lives of infants, children, and young adults.

An American mother now has better than 999 chances out of 1,000 to come through childbirth safely. This is the best record in our history and, on a comparable basis, the best in the world. In the 10 years between 1940 and 1950, infant mortality was cut 38%. At the present rate of progress the record of the United States should be shortly, if not already, the best in the world. A baby born today has more than 20% greater chance of reaching maturity and almost 45% greater chance of achieving the age of 50 than had a baby born in 1900. At the same time, he faces only about half the hazard of becoming an orphan before reaching maturity.

THE CHOICE IS ACHIEVEMENT VERSUS SOCIALISTIC EXPERIMENT

I believe the mothers of America will consider that these achievements far outweigh the empty promises of those who urge a system of government-controlled medical care. We cannot afford to sacrifice this record upon the altar of socialistic experiment.

A recent survey conducted by the World Medical Association among the professions of 40 countries, disclosed that the United States was the country preferred for postgraduate study and specialty training. This country has the finest medical schools, the most modern and efficient hospitals, the best trained and most competent medical profession and by far the highest standard of medical care the world has ever known.

I should like to underscore the next statement. The American people are entitled to this assurance: *No health crisis or medical emergency exists in this country.* We are proud of the part the American Medical Association has played in this record of progress.

A. M. A. GROWS AS A GREAT PUBLIC SERVICE ORGANIZATION

As our country has grown and changed from a rural to a mixed industrial and agricultural economy, the problems of medical care have multiplied. The American Medical Association has grown and developed correspondingly during the same period. Few Americans know of the extensive activities of the Association devoted to their welfare. Few realize the degree to which it is a great public service organization. The nine-story headquarters building in Chicago houses more than 800 employees, working full time on projects which are directly or indirectly in the public interest.

Early in the present century, medical education in this country was in a deplorable condition. "Diploma mills" and second and third rate schools flourished. The American Medical Association, in cooperation with others, established sound educational standards and began regular inspection of medical schools. Today, all the medical schools in this country are of high quality and are turning out splendid physicians. This is one of the main reasons why medical science has progressed so rapidly in the United States during the past 30 years.

A MEDICAL F. B. I. PROTECTS THE PEOPLE

For the past 50 years, the Association has worked for high standards in the manufacture of drugs and appliances. The American Medical Association itself tests hundreds of drugs and appliances every year. Its seal of approval upon such products assures the profession and the laity, alike, of high quality.

The Association operates what might be described as a medical F. B. I., which investigates and exposes quack doctors and fake remedies. Every year many worthless medicines and treatments appear upon the scene. The American Medical Association cooperates with law-enforcing agencies throughout the country in securing withdrawal of such remedies and in exposing quack practitioners.

A. M. A. FUNDS FOR MEDICAL RESEARCH AND EDUCATION

On the other hand, the Association consistently encourages and assists worth while research. Every year the Association spends several hundred thousand dollars to aid research. It was a pioneer in health education, and spends additional hundreds of thousands of dollars annually giving factual health information to the American people through newspapers, pamphlets, radio, television, and motion pictures.

The American Medical Association has promoted the development of sound voluntary health insurance to ease the financial burden of serious illness. As a result of this effort, in conjunction with hospital groups, insurance companies, labor, industry and others, there has been tremendous growth of this type of coverage. Today, more than 72 million people have some type of voluntary protection against the financial shock of illness. We shall continue our efforts to expand and improve prepaid medical care, and confidently look forward to the enrollment of the vast majority of our people in voluntary plans within the next few years.

PRIVATE ENTERPRISE IS SOLVING THE ECONOMIC PROBLEM OF ILLNESS

I can make this flat declaration: *The problem of insurance against the economic hazards of illness is well on its way to orderly solution within the existing framework of private enterprise.*

One of the most important tasks of the Association is to keep its members informed of the latest developments in medical science. To this end, it holds two large meetings each year. The physicians learn by hearing papers presented by leaders of the profession, viewing films and television portrayals of surgical and diagnostic procedures and by wandering through miles of medical exhibits. One physician recently described such a meeting as "a complete postgraduate education under one roof."

To inform the physician who cannot attend these meetings and to eliminate delay in presenting new discoveries made between meetings, the Association regularly publishes ten scientific journals and several books. The weekly JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION is the most widely read and most highly esteemed of all medical periodicals.

What do these activities mean to you, the public? These services of the American Medical Association keep *your* doctor up to date through his years of practice so that he may render the best medical care to you and to your family.

A. M. A. WORKS IN ALL FIELDS OF HEALTH

The Association is concerned with the health problems of *all* segments of society. It studies industrial hazards, cooperates with labor and management to eliminate them, and holds an annual conference on industrial health. It does similar work in the field of rural health, where it works with those organizations interested in rural problems. It has helped design plans for placing doctors in rural areas where they were needed.

The Association is currently studying means of improving services for those in the lower income brackets. It is one of the co-sponsors of the Commission on Chronic Illness, which studies diseases of long duration, particularly those of the aged. One council is devoted entirely to the problems of civil defense and the armed forces. Another bureau compiles and analyzes medical statistics. It recently completed the only national study of blood banks which has ever been made. The nation is now in a position to know the requirements for blood and the sources of supply.

AVAILABILITY OF GOOD MEDICAL CARE CONSTANTLY INCREASING

In medical problems that are best solved at the local level, the Association serves in a coordinating and advisory capacity to state and county societies. It urges programs such as that to make medical care available at any hour by the establishment of night and emergency call systems in all communities.

Another project is the nationwide development of grievance committees, to hear and act upon complaints which patients may have concerning any aspect of medical service. Thirty-six states now have such committees.

There are many other public service projects of the American Medical Association, but this brief discussion perhaps will demonstrate the substantial contribution which organized medicine *has made* and *is making* to America's health. Problems still exist, and no one is more aware of them than the medical profession. Certain rural areas and some government services need more physicians, but there is no real shortage of physicians. The United States has more doctors than any country and except for Israel, where an abnormal situation exists, a higher ratio to the population than any nation.

COOPERATION SOLVING PROBLEM OF DOCTOR DISTRIBUTION

Medical care is less available in certain areas than in others. However, the American Medical Association and the state and county societies are assisting such communities to obtain more doctors. They endeavor to bring together the doctors seeking places to practice and the localities in need of physicians.

The problem is one of distribution rather than shortage. Significant improvement has taken place and is continuing, as a result of the cooperation of the branches of medical organization with the local communities in need.

Looking toward the future, the American Medical Association favors training of more physicians. Our medical schools have expanded their enrollments. At this time, there are more students preparing for careers in medicine than at any time in our history, and by 1960 we will be producing at least 30% more physicians than we did in 1950. This tremendous growth will be accomplished without sacrifice in the quality of education. To fail to maintain our present high standards would be ruinous to the future of medical care.

A. M. A. STIMULATES PRIVATE SUPPORT FOR MEDICAL SCHOOLS

Some of our medical schools, however, are in financial distress. This is a matter of deep concern to the American Medical Association. In appreciation of this situation, the Association has donated a half million dollars in an effort to stimulate realistic private support for medical education. Other societies have contributed lesser amounts. On May 16 last, the Foundation created by the Association was merged with the National Fund for Medical Education headed by Mr. Herbert Hoover. I urge every physician to contribute promptly and generously.

In addition, we advocate one-time federal grants for necessary remodelling and construction. The Association believes that medical education can be financed adequately by these means and without danger of federal control. We recognize the great service to medical advancement rendered by our full-time basic science and clinical teachers, and seek to improve their opportunities.

AMERICAN MEDICINE DEDICATED TO HIGH PURPOSES

In a changing world, nothing is static and new problems will arise. Physicians do not issue careless statements concerning the health of an individual or a nation. I make no irresponsible, utopian promises, but I assure you that we are attacking the problems confronting us with the same determination that has characterized our battle against disease.

I am proud to serve as President of the American Medical Association. It is a truly American institution, democratic in organization and dedicated to high purposes. It has one hundred forty odd thousand members—the vast majority of American physicians engaged in the care of the sick. The greatness of American medicine is inseparable from the over-all greatness of America. It has sprung from the same freedom which has made possible the attainment of high standards in all fields of endeavor.

PHYSICIANS, AS CITIZENS, PLEDGE FIGHT FOR AMERICAN FREEDOMS

Democracy and democratic institutions are on trial. It is an historical fact that men must control themselves and their destinies or be controlled by others. The philosophy of statism is foreign to the American concept of life.

American medicine eagerly assumes its responsibility to provide medical care of ever higher standard for the American people and to bring that care progressively within easier reach of those who require it. At the same time, the physicians of this country pledge themselves to dynamic activity as citizens to preserve the freedom which is requisite to the fulfilment of their medical obligations to the American people.

TREATMENT OF RHUS DERMATITIS

Colonel Robert J. Hoagland, Captain Paul W. Myers, United States Air Force,
and
Captain Henry C. Cosand, Medical Corps, United States Army

Numerous treatments for Rhus dermatitis are mentioned in textbooks of dermatology, and a writer on the subject is likely to be surprised by interest shown by the lay press and by many laymen volunteering cures involving various herbs or chemicals. The many remedies advocated by physicians and the laity testify both to unscientific thinking and to difficulties involved in controlled investigations.

Treatment of 70 patients with ivy dermatitis with tripelennamine (pyribenzamine®) hydrochloride cream and calamine lotion, in the summer of 1949, led to the conclusions that further trials with tripelennamine locally were desirable and that a local anesthetic such as dibucaine (nupercainal®) would be preferable to calamine lotion for comparison with agents believed to have curative effects.[1] In addition, investigation of other recommended remedies might result in finding a treatment that could be shown to accelerate recovery from Rhus dermatitis.

Investigation and evaluation of a proposed treatment for ivy dermatitis is made unusually difficult by individual variations in types of lesions resulting from exposure. For example, some patients have chiefly papular lesions; others have blebs, vesicles and oozing lesions; still others have a cellulitis type of reaction. A few patients complain of intolerable pruritus, but some have little or no itching. The final extent of involvement and ultimate severity of the disease cannot be estimated accurately when the patient is first seen, because new lesions often continue to appear for several days after exposure. Furthermore, trauma produced by scratching during sleep and secondary infections may unpredictably delay recovery. For these reasons, comparisons of different modes of treatment in different patients are either valueless or misleading. Comparisons of new treatments with treatments used on previous occasions by the same patient are invalid because the degree of dermatitis in previous attacks is not known to the investigator, the susceptibility of patients is variable, and patients' memories are unreliable. Successive use of different medications on the same lesion cannot lead to valid conclusions because the first medicament is usually applied while the disease is in ascendancy, whereas later treatments merely coincide with spontaneous recovery. Finally, unless patients are carefully observed, one cannot be certain whether the remedies prescribed are being properly used and, of greatest importance, whether subjective improvement is reflected in rapid healing.

From the United States Army Hospital, United States Military Academy, West Point, N. Y.

The dibucaine ointment (nupercainal®) and tripelennamine (*pyribenzamine*) cream used were furnished by Ciba Pharmaceutical Products, Inc., Summit, N. Y. Tannic acid solution, 5 per cent, containing chlorothen, 2 per cent, and phenol, 0.4 per cent (rhulitol® containing chlorothen) was supplied by Lederle Laboratories Division, American Cyanamid Company, Pearl River, N. Y., and a compound of hydrogen peroxide, acetanilid not over 0.017 per cent, acetic acid, benzethonium chloride 0.75 per cent and propylparahydroxybenzoate 0.02 per cent (neoxyn®) was furnished by William H. Rorer, Inc., Philadelphia, Penn.

[1] Hoagland, R., and Myers, P.: Treatment of Rhus Dermatitis, U. S. Armed Forces M. J. (May) 1950.

A review of the literature reveals inconsistent statements, unproved opinions, and uncritical conclusions regarding the prophylaxis, treatment and duration of Rhus dermatitis. For example, Alderson,[2] Bivings [3] and Caulfeild [4] recommended the use, orally and intramuscularly, of extracts of Rhus toxicodendron in treatment, but they used no control cases, whereas Howell,[5] using control patients, showed that there was no significant difference in the rate of healing between groups receiving and not receiving injections. He concluded that the fundamental basis for treatment with intramuscular injections of poison ivy extract was unsound and that this treatment was contraindicated. Sharlit and Newman [6] gave 74 patients injections of an extract of poison ivy and gave eight control subjects injections of absolute alcohol. They concluded that their extract was curative in cases of Rhus dermatitis, but their criterion of effective therapy was cessation of symptoms and of further spread of inflammatory reactions, not acceleration of recovery in comparison with that in controls.

Our observations, over five years, indicate that differences in statements regarding the usual duration of Rhus dermatitis are explained by differences in offending plants and in intensity and durations of exposure, individual differences in hypersensitivity and reaction and in the extent and locations of lesions. The importance of intensity and duration of exposure was dramatically demonstrated by Molitch and Poliakoff,[7] who stated that patients inoculated with poison ivy extract remained free of the disease despite playing in an environment containing poison ivy, but incurred severe dermatitis when they held plants for 30 seconds.

Witherspoon [8] advocated the use of a cream containing 1 per cent menthol or phenol and 10 per cent sodium perborate but used no controls. Of 70 patients, 90 per cent were clinically cured in five to seven days, but in none was the disease severe enough to warrant hospitalization. Results of treatment of hospitalized patients with severe involvement were not stated, although such patients received similar treatment. Blumenthal and Rosenberg [9] reported relief from pruritus in 12 of 14 patients given 50 mg. of diphenhydramine hydrochloride orally every four to six hours, but they did not describe the severity of the disease. Tweedall and O'Connor [10] gave 100 mg. of tripelennamine hydrochloride orally one hour before applying an extract of Rhus toxicodendron to five persons who had strongly positive patch tests for this substance, and 50 mg. at the time of application as well as every four hours for 24 hours. They observed only moderate relief from burning and itching and no prevention of dermatitis. Furthermore, in 1946 we used diphenhydramine orally for Rhus dermatitis, in doses identical to those used by Blumenthal and Rosenberg, without subjective or objective improvement. Philip [11] treated 11 patients having Rhus dermatitis with diphenhydramine cream and reported disappearance of weeping and itching within 36 hours in eight patients; however, three patients had symptoms for eight days. Only two controls were reported. Sulzberger, Baer and Levin [12] used tripelennamine ointment locally for various skin disorders, but not for Rhus dermatitis, and reported that it produced an eczematous allergic reaction in two of 90 patients. Strauss [13] confirmed this observation and showed that tripelennamine, not the vehicle for the drug, produced an acute, oozing, edematous dermatitis. Four of 70 patients studied by us in 1949 also experienced irritation from tripelennamine. Ethyl chloride spray was used on 101 patients by Robinson,[14] who reported good results but used no controls.

TECHNIC OF STUDY

Whenever practicable, areas of Rhus dermatitis of about equal duration and intensity, on the same patient, were chosen for treatment with different medicaments and were examined daily. When areas of equal intensity could not be found, a patch of dermatitis was divided with an indelible line into equally involved areas. The halves of the area were treated differently. The following remedies were used: 2 per cent tripelennamine cream, dibucaine ointment and a 5 per cent tannic acid solution plus chlorobutanol 1 per cent, phenol 0.4 per cent, camphor ammonium alum and isopropyl alcohol 39.5 per cent (rhulitol®) with chlorothen citrate (tagathen®), a compound of acetic acid, hydrogen peroxide, benzethonium chloride 0.75 per cent, propylparahydroxybenzoate 0.02 per cent, water and aromatics (neoxyn®), 2 per cent zinc sulfate solution and ethyl chloride spray. A total of 92 patients, with 217 involved areas, were treated. The table gives the details of treatment.

Details of Treatment of 217 Areas Affected by Rhus Dermatitis

Medications Used	Number of Areas Treated	Degree of Severity of Dermatitis		
		Mild	Medium	Severe
Tripelennamine cream............	47	24	13	10
Dibucaine ointment...............	37	21	11	
Tannic acid with chlorothen......	52	21	22	
Propylparahydroxybenzoate	43	14	22	7
Zinc sulfate solution.............	32	15	11	6
Ethyl chloride spray..............	6	5	1	0

RESULTS

Twenty-seven patients with paired lesions of about equal severity were treated with tripelennamine cream and dibucaine ointment. In 15 instances the results were about the same. In 10 instances tripelennamine cream, and in two instances dibucaine ointment, appeared to accelerate healing slightly. In this group, as well as in all of the cases outlined below, the use of no medication was followed by dramatically swift recovery.

Twenty-five patients received tripelennamine cream and tannic acid, 5 per cent, with chlorothen, on paired lesions. In 21 instances the results were about the same, and of the remaining four two appeared to respond better to tripelennamine, whereas the other two appeared to respond better to tannic acid.

Twelve patients received tannic acid with chlorothen and a 2 per cent zinc sulfate solution on paired lesions. Half of these had approximately equal effects from each; tannic acid appeared to be superior to zinc sulfate in four instances, and the opposite result was obtained in 2 instances.

Propylparahydroxybenzoate and 2 per cent zinc sulfate solution were used on eight patients with equally involved areas; there was no discernible difference in results.

Tripelennamine cream and propylparahydroxybenzoate were used in 2 paired cases with no apparent difference in results.

Tannic acid with chlorothen appeared to be slightly superior to propylparahydroxybenzoate in all of five patients who received these medicaments on paired lesions.

Five patients receiving tannic acid with chlorothen and dibucaine ointment appeared to derive about equal benefit from both treatments.

Only two patients received propylparahydroxybenzoate and dibucaine ointment on equally involved areas; one appeared to benefit more from the former and one from the latter treatment.

Six patients had lesions treated with ethyl chloride spray, while similarly involved areas were treated with dibucaine ointment. No patients derived benefit from the spray, and three spray-treated areas were irritated and healed slowly.

Evaluation of the effect of these medicines on itching was difficult. In general, it could be said that all were antipruritic and that propylparahydroxybenzoate, ethyl chloride, and zinc sulfate were the least effectual. Tripelennamine cream, dibucaine ointment and tannic acid compound with chlorothen were approximately equally effective as antipruritics.

COMMENT

Rhus toxicodendron dermatitis resembles a burn in that the skin is exposed to a noxious agent, and, as a result, a relatively unalterable sequence of changes manifesting reaction and repair is set in motion. No locally applied medications used by us—including tripelennamine cream, anesthetic creams, zinc sulfate solution, tannic acid solution with chlorothen, propylparahydroxybenzoate and ethyl chloride spray—dramatically accelerated healing. Patients often speak of remedies acting promptly to effect recovery, "drying up the rash almost overnight." We could not demonstrate such effects. The antihistamine medications appeared to speed healing slightly in some instances, but in over half of the cases their effect was no better than that of agents that had no antihistamine action.

Itching and burning pain are the two chief subjective complaints. They are, however, not uniformly present. When these symptoms occurred, they were usually alleviated, at least partially, by any one of the medications used, except ethyl chloride spray, which was practically worthless; a 2 per cent zinc sulfate solution was of little value. A 5 per cent tannic acid compound with an antihistamine (rhulitol® with tagathen®), 2 per cent tripelennamine cream, dibucaine ointment, and the hydrogen peroxide, benzethonium, acetic acid compound, propylparahydroxybenzoate, were most effectual in lessening symptoms.

Application of moist warm compresses accelerated recovery when used on cellulitis-like lesions characterized by swelling, local heat and redness. Patients with severe dermatitis may have such inflammatory lesions without secondary infection. The latter are effectively treated with systemic use of penicillin or aureomycin, and aureomycin ointment applied locally, not available at the time of this investigation, merits trial.

SUMMARY AND CONCLUSIONS

1. Ninety-two patients with 217 areas of Rhus dermatitis were treated with: 2 per cent tripelennamine pyribenzamine hydrochloride cream, dibucaine ointment, a 5 per cent tannic acid solution (Rhulitol®) with chlorothen (tagathen®), a compound of acetic acid, hydrogen peroxide, benzethonium chloride and propylparahydroxybenzoate, 2 per cent zinc sulfate solution and ethyl chloride spray.

2. Accurate evaluation of proposed treatments for Rhus dermatitis is difficult, because many variables are involved—for example, individual susceptibility and reaction; extent and duration of exposure to plants; secondary trauma, and duration of dermatitis before treatment.

3. Comparisons between different medications or different individuals are invalid. Only if approximately equally affected and equally old areas of dermatitis on the same patient are treated differently and simultaneously can reliable comparisons and conclusions be made. Ninety-two patients had paired areas of dermatitis, equivalent in duration and intensity of dermatitis, treated concurrently with two medications.

4. The speed of recovery from Rhus dermatitis is not dramatically influenced by any agent applied to the skin's surface, but it may be accelerated (at least in cellulitis-like lesions) by application of warm moist compresses, and, in some patients, to a slight degree by locally applied antihistamines.

5. Treatments recommended in Rhus dermatitis are creams or solutions containing local anesthetics, perhaps wtih antihistamines, and warm, moist compresses for cellulitis-like or oozing lesions.

The Physician's Features.—No matter how hard he [the patient] stares at your countenance, he should never be able to read his fate in it. It should be cheerful as long as there is hope, and serene in its gravity when nothing is left but resignation. The face of a physician, like that of a diplomatist, should be impenetrable. Nature is a benevolent old hypocrite; she cheats the sick and the dying with illusions better than any anodynes. If there are cogent reasons why a patient should be undeceived, do it deliberately and advisedly, but do not betray your apprehensions through your tell-tale features.—Oliver Wendell Holmes, Medical Essays, Boston, Houghton, Mifflin & Company 1883, p. 387.

DRAMATIC RESPIRATORY SYMPTOMS INDUCED BY SUDDEN WITHDRAWAL OF ACTH

Robert W. Keeton, M.D., William R. Best, M.D., Ford K. Hick, M.D., M. M. Montgomery, M.D.
and
Max Samter, M.D., Chicago

Untoward side effects are major obstacles to the prolonged administration of pituitary adrenocorticotropic hormone (ACTH). Although most of these effects are due to excessive release of corticoids, there is increasing evidence that prolonged administration of the hormone has a profound effect on both the anterior pituitary and the adrenal cortex. In most instances, functional deficiency of the glands remains on a subclinical level. It seems, therefore, justifiable to report two cases, both of respiratory impairment, in which withdrawal of the drug caused severe clinical manifestations.

REPORT OF CASES

Case 1.—The first patient, E. F., a 48 year old white male, has had a progressive, severe pulmonary fibrosis of unknown etiology for four years. In 1949, six months prior to administration of the hormone, he developed cor pulmonale with mild cardiac decompensation. Prior to administration of the drug he was dyspneic, had frequent coughing spells, complained of marked nasal congestion and was unable to engage in minimal activities. Twenty mg. of pituitary adrenocorticotropic hormone administered three times daily, resulted in objective improvement within 48 hours—his nasal passages cleared; his breathing improved noticeably; his cough stopped; he experienced a pronounced feeling of well-being and was soon able to resume moderate activities.

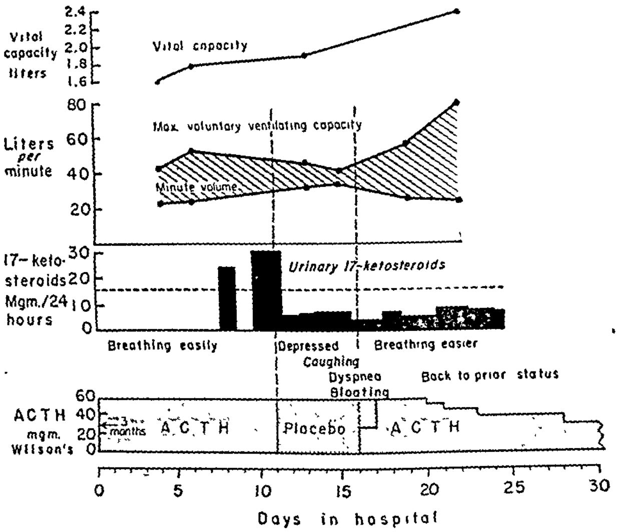

Fig. 1.—Hospital course of patient E. F., who has pulmonary fibrosis.

The hormone was discontinued after two months of therapy, and within 36 hours dyspnea and episodes of coughing returned. The patient became depressed, and then hysterical. His condition deteriorated so rapidly that hormone therapy was resumed, with rapid improvement in his physical and mental status.

In order to study the mechanism of this reaction, he was hospitalized one month later at the Research and Educational Hospitals. He was continued on 20 mg. of the drug, three times daily, for 11 days. The urinary excretion of 17-ketosteroids suggested an adequate adrenocortical response (fig. 1). On the twelfth day, placebo injections were substituted for the hormone without the patient's knowledge. Forty-eight hours later a marked mental depression became evident, a slight cough was present and breathing became more difficult. Dyspnea and coughing increased during the next two days. He was not cyanotic. His pulse rate was 124, his respirations were 36 per minute and his temperature was 100.2 F. Treatment with the drug was resumed, and again he recovered within 48 hours. After recovery there was a gradual decrease in minute volume, accompanied by an increase in vital capacity and maximum voluntary ventilating capacity beyond the level established prior to the administration of the placebo. Since then the dosage of the drug has been gradually reduced, and he is at present receiving 30 mg. in divided doses.

Case 2.—The second patient, E. U., a 58 year old man, has had chronic bronchitis with secondary emphysema for 10 years. Dyspnea has become progressively more severe during the past eight years. Prior to the administration of pituitary adrenocorticotropic hormone, minimal efforts, such as shaving or walking a few yards, produced marked shortness of breath. He was admitted to the Research and Educational Hospitals, and, after a suitable control period, was given 40 to 60 mg. of the drug, first in the hospital, then at home, over a 45 day period. Improvement was slight, in spite of the increased excretion of 17-ketosteroids in the urine (fig. 2). Improvement did not seem to warrant further administration of the hormone. Seventy-two hours after sudden and complete withdrawal of the drug, he became weaker and very dyspneic. His condition became rapidly worse and from the fourth to the eighth day he required continuous oxygen. At this time he was readmitted to the hospital in a critical condition. He was very weak, severely dyspneic, coughed frequently and his face had an ashen color. His temperature was 101.4 F., his pulse rate was 126 per minute and his respirations were 36 per minute. His blood pressure was 152/110. A chest roentgenogram showed no change. Electrolyte studies on admission were normal. Streptomycin and aureomycin were started immediately, without apparent effect. Twenty-four hours after the patient's admission to the hospital, the drug was resumed without his knowledge, and within another 24 hours his clinical condition improved noticeably. Three days later he felt about the same as he had prior to withdrawal of the hormone. 17-Ketosteroids determinations, though not obtained during the drug-free interval, did not rise

in proportion to clinical improvement during the second course of therapy. The drug was very gradually withdrawn over an 18 day period without incident.

COMMENTS

The histories of these two patients raise two major questions: First, what is the mechanism responsible for the dramatic collapse of the patient on withdrawal of pituitary adrenocorticotropic hormone? Second, what factors are responsible for the almost immediate and rapid improvement after resumption of therapy?

Treatment with corticotropin produces a hypofunction of the pituitary gland with decreased secretion of endogenous pituitary adrenocorticotropic hormone. When corticotropin is suddenly withdrawn, this deficiency of the endogenous hormone results in a secondary hypoadrenalism. On the other hand, if pituitary adrenocorticotropic hormone is gradually withdrawn, the glands adapt themselves to their pretreatment capacity. Thorn has called attention to the so-called adrenal atrophy during and following cortisone therapy. His statement—presented during an informal discussion at the First Conference on the Adrenal Cortex, of the Josiah Macy, Jr., Foundation—reads:

> You treat for two weeks with 100 mg. of Cortisone. You then stop treatment. For two to five days you will fail to get an adequate adrenal cortical response to the ACTH test. In other words, the adrenal has atrophied and it won't be brought back very easily by the ACTH during that period. I don't know just how long the period lasts. We have had cases that we are trying to follow. You can see after you stop the Cortisone treatment that you are going to have the widest possible swing, because within two or three days you are going to go from essentially a Cushing's down almost into an Addison's range of adrenal secretion. You just hope that nothing happens to the patient during the week after you stop your Cortisone therapy.

One must realize, however, that Thorn's statement is based essentially on treatment with cortisone, not with pituitary adrenocorticotropic hormone.

In our patients, the rapid recovery after resumption of pituitary adrenocorticotropic hormone therapy leads us to believe that we are dealing with a pituitary rather than an adrenal cortex deficiency. Patients with bronchial asthma respond spectacularly to the hormone but frequently relapse on its withdrawal. One might reason that the pulmonary tissue is particularly vulnerable to sudden deficiencies of glucocorticoids; on the other hand, defenses against infections are profoundly modified during and after the administration of pituitary adrenocorticotropic hormone. It seems that interference with these defenses might be responsible for some of the features in the serious reactions which we have observed. This problem needs further investigation. We are presenting this clinical report because we feel that the possibility of producing serious clinical withdrawal symptoms after prolonged treatment with the hormone should be brought to the attention of clinicians using it.

SUMMARY

Two patients with respiratory impairment showed dramatic respiratory symptoms induced by sudden withdrawal of pituitary adrenocorticotropic hormone. Both responded to readministration of the hormone. Subsequent gradual withdrawal of the hormone was accomplished without incident in one patient. The other patient is still receiving the hormone in therapy. The clinical histories which we have presented suggest that withdrawal of the drug in patients with pulmonary disease should be carried out with great caution.

HEMORRHAGIC PERICARDITIS IN ACUTE MYOCARDIAL INFARCTION TREATED WITH BISHYDROXYCOUMARIN

Robert Goldstein, M.D.
and
Louis Wolff, M.D., Boston

The reports of the Committee for the Evaluation of Anticoagulants in the Treatment of Coronary Thrombosis with Myocardial Infarction, American Heart Association, and several other reports [1] have indicated the efficacy of anticoagulant therapy in acute myocardial infarction. The drug of choice at the present time is bishydroxycoumarin (dicumarol®). Its toxicity has been studied in animals,[2] and the hemorrhagic complications that occur clinically have been reported. It is the purpose of this communication to call attention to an unusual and serious hemorrhagic complication heretofore unreported and to emphasize the clinical signs that make possible early recognition of this complication.

REPORT OF CASES

Case 1.—This was the first admission to the hospital of a 42 year old white man, who entered with severe substernal pain of one hour's duration. He had had no previous history of exertional dyspnea, chest pain, peripheral edema, diabetes or hypertension. On the morning of admission, while driving his car, he suddenly experienced severe squeezing pain over the precordium and sternum, which radiated into the left shoulder and down the left arm. This was accompanied with profuse sweating, weakness and nausea. The pain persisted until the time of admission.

Examination revealed an apprehensive man complaining of severe pain in the chest. There was no engorgement of the neck veins; slight cyanosis was evident. The heart was not enlarged, the rhythm was regular, the heart sounds were distant and the first apical sound was split. There were no murmurs, thrills or friction rub. The blood pressure was 95/65 in both arms. There were fine moist rales at base of each lung. The liver and spleen were not palpable, and there was no peripheral edema. The white blood cell count was 11,000 per cubic millimeter. The corrected sedimentation rate was 0.9 mm. per minute (Rourke-Ernstene

method,[3] normal 0.08 to 0.35 mm. per minute). The urine was normal. The electrocardiogram showed changes characteristic of an acute posterior myocardial infarct.

The initial treatment consisted of bed rest and use of oxygen and morphine. Bishydroxycoumarin, 300 mg., was administered on the first day immediately after the determination of the prothrombin time. The drug was administered daily thereafter in doses calculated to maintain the prothrombin time between 30 and 35 seconds (5 to 10 per cent prothrombic activity according to the Rosenfield and Tuft method) [4] (table1).

During the first six hospital days the temperature ranged between 101 and 102 F. and then gradually fell, reaching normal on the eleventh day (fig. 1). Basal rales and slight cyanosis persisted despite continuous administration of oxygen. On the third hospital day a pericardial friction rub was first noted. The rub was heard at all examinations over the entire precordial area, from the third to the twelfth hospital day; after this period it was no longer audible. On the fourth hospital day moderate icterus was noted and the liver was palpated 2 fingerbreadths below the right costal margin. The urine gave a positive test for bile.

At the end of the first week, the patient was free of pain; the lungs were clear and cyanosis was absent. By the ninth hospital day jaundice was no longer detectable and the urine was free of bile. The blood pressure during this period was 100-110/60-70.

The temperature rose to 101 F. on the thirteenth hospital day. The following day, the prothrombin time was 45 seconds, and bishydroxycoumarin was not given. On the morning of the fifteenth day, rales at base of each lung and slight cyanosis were again noted and the prothrombin time was 40 seconds. A few hours later, anterior chest pain recurred and lasted approximately one-half hour; relief was then obtained with meperidine hydrochloride. Shortly after the onset of pain, there was a fall in the blood pressure to 90/80. This level was maintained until early morning of the sixteenth hospital day, when there was more profound vascular collapse. It was noted that all superficial veins were distended. The prothrombin time was 67 seconds, although bishydroxycoumarin had not been given the previous two days. There were no overt hemorrhagic manifestations. The patient was given 100 mg. of menadione sodium bisulfite and 200 cc. of stored plasma intravenously during the course of the next few hours, after which the prothrombin time was 31 seconds. The patient failed to respond to therapy and died at 7 p. m. on the sixteenth hospital day.

Postmortem Examination.—The pericardium was found to be firmly adherent over the greater part of the left ventricle, except toward the base and over the septum anteriorly. It was also adherent over the posterior surface of the right ventricle, extending to the apex, over the auricles and to its reflexion at the great vessels. Six hundred cubic centimeters of bloody fluid were present in the free pericardial space. The hematocrit value of this fluid was 45 per cent. The addition of either 1 or 10 units of thrombin to 1 milliliter of the pericardial fluid caused no clot formation, thus indicating the absence of fibrinogen. No prothrombic activity could be demonstrated in the pericardial fluid by the Rosenfield and Tuft modification of Quick's one stage method.[4] After the bloody fluid was removed, there remained a thick, heavy, fibrinous, partially organized exudate. In the adherent areas, the pericardium stripped with difficulty, leaving a partially organized blood clot on the epicardium.

The left ventricular myocardium, except for the anterior portion toward the base, appeared to be involved in a recent infarction characterized by blue-black discoloration and thinning of the myocardium. The cut surfaces revealed necrosis and gelatinous degeneration. Both papillary muscles were involved. The posterior portion of the right ventricle, the apex and the entire length of the septum posteriorly were also involved in this process. The papillary muscles in the right ventricle appeared normal. No perforations, tears or ruptures of the myocardium or coronary vessels were found after careful examination, and leakage of the injection mass into the myocardium was not observed.

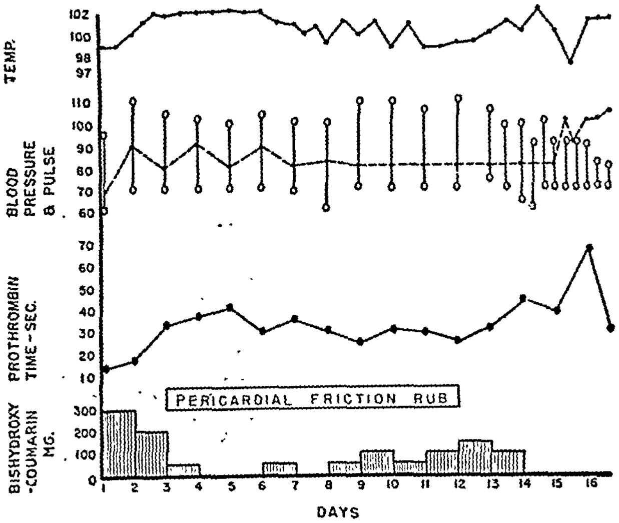

Fig. 1.—Clinical course in case 1.

Injection and dissection of the coronary arteries according to the Schlesinger technique [5] revealed atheromatous plaques and slight narrowing along the entire length of the main left anterior descending artery. The left circumflex artery was essentially normal. Atheromatous plaques in the main right coronary artery caused moderate narrowing of the vessel up to an occlusion 5 cm. from the mouth of the vessel. The occlusion was caused by an organized adherent thrombus 0.9 cm. in length, surrounded by an atheromatous abscess. Just distal to the occlusion there was a tail-like, nonadherent, nonoccluding thrombus, the base of which was partially organized and attached to the

previously described thrombus. All vessels distal to this point were injected by the mass from the left coronary artery. Microscopic sections revealed both a healing and a fresh infarct in the areas of gross change noted above; the latter appeared to be of about 24 hours' duration.

On gross examination, the liver appeared slightly firmer than normal and there was congestion of the central veins. Microscopic examination revealed early acute central necrosis. Gross and microscopic examination of the kidneys and other organs revealed no abnormalities.

Case 2.—A 66 year old white woman was admitted to the hospital after an episode of chest pain. There was a 25 year history of moderately severe bronchial asthma and at least a 10 year history of hypertension; she had had albuminuria six years prior to the attack. Forty-eight hours before admission, substernal and left chest pain occurred suddenly. The pain was cutting in character and nonradiating. It lasted approximately two hours and was associated with sweating and vomiting. It was relieved by morphine and thereafter did not recur.

On admission, examination revealed an obese white woman who was moderately dyspneic and slightly cyanotic. Respirations were wheezing. The blood pressure was 180/100. The heart was moderately enlarged to the left. The rhythm was regular, with an occasional premature beat. The heart sounds were masked by the wheezing respiration. The anteroposterior diameter of the thorax was increased. There were loud ronchi and wheezes throughout both lung fields. The liver was felt 2 fingerbreadths below the right costal margin but was not tender. There was no icterus or edema. The white blood cell count was 43,400 (polymorphonuclear cells 79 per cent, band forms 6 per cent, lymphocytes 6 per cent and monocytes 8 per cent) and remained elevated during the entire period of hospitalization. There were no abnormal cells in the peripheral blood smear. The urine contained albumin (4 +) and 8 to 10 white blood cells per high power field in an uncatheterized specimen. The specific gravity ranged from 1.010 to 1.020. The electrocardiogram was characteristic of posterior myocardial infarction and complete auriculoventricular block.

Table 2.—*Prothrombic Response to Therapy*

Therapy consisted of bed rest and administration of oxygen, codeine, penicillin, potassium iodide and small doses of epinephrine (adrenalin®) in oil. Bishydroxycoumarin, 300 mg., was administered on the evening of admission. Within 36 hours of this single dose, the plasma prothrombic activity had fallen to 4 per cent as determined by the Rosenfield and Tuft technique[4] and, except for a single determination of 40 per cent on the fifth hospital day, remained below 5 per cent for the duration of hospitalization, despite the administration of only one additional dose of 50 mg. of bishydroxycoumarin on the fifth hospital day (table 2). Whether the finding of 40 per cent prothrombic activity on the fifth hospital day was a laboratory error, a response to the small dose of menadione sodium bisulfite (4.8 mg.) given on the previous day, or a representation of the wide fluctuations in prothrombic activity not infrequently observed, cannot be stated.

The temperature fell from a level of 101 F. to normal within 24 hours and remained there. The pulse rate ranged between 45 and 60, as the complete auriculoventricular block persisted. There was evidence of moderate renal insufficiency, with nonprotein nitrogen values ranging from 50 to 60 mg. per 100 cc., and was 54 mg. seven hours before the patient's death.

The asthma was easily controlled, and only small doses of epinephrine in oil were necessary (0.3 cc. of a 1: 500 suspension) on the first, second and fifth hospital days. The heart sounds, which on the first day were obscured by the respiratory wheezes, were of poor quality. At no time was a pericardial friction rub heard. On the eighth hospital day the patient became lethargic and there was a marked decrease in urinary output. These symptoms persisted despite intravenous administration of fluids. On the eleventh hospital day the patient complained of severe periumbilical pain, but there were no abnormal abdominal signs. The white blood cell count, which had gradually fallen from a level of 43,400 on admission to 13,000 on the tenth hospital day, rose to 33,800. Peripheral vascular collapse occurred shortly after the onset of pain. Within a few hours the blood pressure, previously maintained at a level of 130/80, was unobtainable. The patient failed to respond to therapy and died on the eleventh hospital day.

Postmortem Examination.—The pericardial cavity was almost completely obliterated by numerous dense fibrous adhesions. The pericardium was separated with great difficulty, and in several areas over the anterior surface the epicardial and parietal layers were so densely adherent that they were removed together from the myocardium. In a few areas posteriorly, where free pericardial space still persisted, there was an accumulation of 50 to 75 cc. of bloody fluid, and when this was removed a partially organized blood clot on the epicardium was noted. Careful examination revealed no evidence of rupture, tear or perforation of the myocardium or coronary vessels.

The heart weighed 470 Gm. On gross examination there was evidence of an extensive myocardial infarct involving the posterior wall of the left ventricle, the posterior portion of the interventricular septum and the posterior papillary muscle. Microscopic examination revealed massive infarction involving the posterior wall of the left and right ventricles, the interventricular septum, the posterior papillary muscle and the left atrium. The right ventricular extension of the infarct was recent and appeared to be less than 24 hours old. In this area of recent infarction several small veins contained fibrin thrombi. The epicardium was covered by a heavy layer of fibrin, which in some areas was overlaid with masses of red blood cells. The inner portion of the epicardium showed organization of the fibrinous exudate. With the exception of the uterus, no other area of hemorrhage was observed. The uterine cavity contained 2 to 3 cc. of bloody fluid. The endometrium was hemorrhagic. The serosal surface of the uterus was normal.

The pancreas appeared normal on gross examination, but the microscopic sections revealed evidence of acute and chronic pancreatitis and acute focal necrosis.

The kidneys were somewhat smaller than average. The right kidney weighed 110 Gm. and the left 130 Gm. There was some thinning of the cortex. Microscopic examination revealed that the renal substance was essentially preserved. There were moderate sclerosis of the interlobular vessel and some focal areas of scarring and tubular atrophy.

The remainder of the examination revealed no significant abnormalities.

The third patient with myocardial infarction and complicating pericarditis herein reported was admitted to the Beth Israel Hospital for the first time shortly after the first patient died. Bishydroxycoumarin therapy was instituted upon admission. The clinical features so closely resembled those of the first case that the diagnosis of hemorrhagic pericarditis appeared likely, although final proof is lacking, since the patient recovered and a pericardial tap was not done.

Case 3.—A 48 year old white man was hospitalized for recurrent chest pain of four days' duration. There was no history of rheumatic fever, hypertension or diabetes. For four years prior to admission he had noted mild anterior chest pain on moderate exertion. Four days prior to admission he experienced pain between the shoulder blades; it had come on suddenly and was aggravated by deep inspiration. Later that day, severe epigastric and anterior chest pain developed and was associated with a feeling of weakness in both arms and legs. Three days prior to admission, the temperature was 103 F. The heart sounds were poor, the patient was cyanotic, and signs consistent with consolidation at the base of the left lung were noted. An electrocardiogram showed changes characteristic of an extensive anterior myocardial infarct (fig. 2).

Examination on his admission to the hospital two days later revealed an acutely ill man with slight cyanosis; the respiratory rate was 25, temperature 103 F., pulse rate 100, and regular, and blood pressure 100/80. There was no engorgement of the neck veins. The heart was enlarged to the anterior axillary line, and a loud to and fro friction rub masked the heart sounds. There was bronchial breathing at the base of the left lung and diminished breath sounds and moist rales at the base of the right lung. The abdominal examination was noncontributory, and there was no peripheral edema. The white blood cell count was 16,000 per cubic millimeter. The sedimentation rate was 2.2 mm. per minute (Rourke-Ernstene method [3]). The urine was normal. The nonprotein nitrogen was 40 mg. per 100 cc. Therapy consisted of bed rest, liquid diet, fluids up to 2,500 cc., meperidine hydrochloride, as necessary, for pain, oxygen and bishydroxycoumarin. The prothrombic activity was maintained generally between 10 to 20 per cent of normal as estimated by the Rosenfield and Tuft technique [4] (prothrombin time between 20 and 30 seconds) (table 3).

During the first 12 hospital days, the patient showed clinical improvement. The temperature fell slowly, reaching normal by the seventh day, and the pulse rate during this period fell from 100 to 70. The chest pain necessitated frequent medication at first but was not troublesome after 72 hours. The cyanosis disappeared within 48 hours, and the use of oxygen was discontinued on the fourth hospital day. The blood pressure was maintained at 100-110/70-80. The friction rub disappeared after the first 24 hours but returned on the fifth day and persisted with varying intensity during and following the first period of clinical improvement.

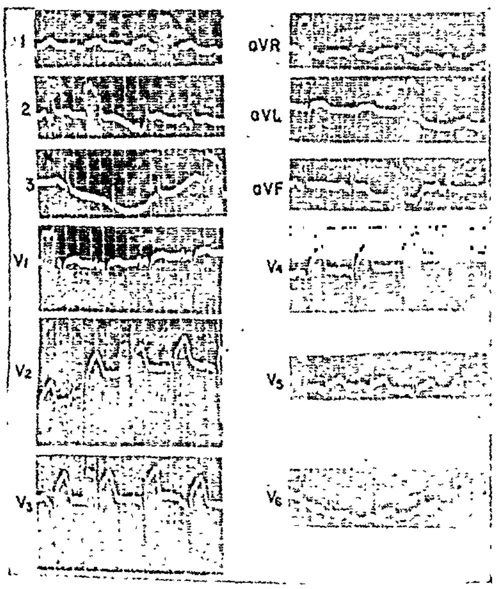

Fig. 2 (case 3).—Electrocardiogram taken after the patient's admission to the hospital, showing changes characteristic of anterior myocardial infarct.

On the afternoon of the thirteenth hospital day, there was a recurrence of anterior chest pain with cyanosis, weakness and profuse sweating. There was no change in the blood pressure, but there was a rise in the heart rate and the friction rub was louder than was previously noted. It was felt that the recurrence and persistence of the friction rub might be secondary to oozing of blood from the inflamed pericardial surfaces and that the sudden deterioration in the patient's condition conceivably was due to profuse bleeding into the pericardial sac. The use of bishydroxycoumarin was discontinued, and 72 mg. of menadione sodium bisulfite was given intravenously on the thirteenth and fourteenth days (table 3). On the fifteenth day the temperature rose to 102 F., the pulse rate to 110 and the respiration rate to 25. Repeated electrocardiograms showed no evidence of fresh infarction. A chest film revealed an increase in heart size when compared with a film taken shortly after admission. These findings were consistent with, but not clearly diagnostic of, pericardial effusion. However, inasmuch as there was no evidence of cardiac tamponade, pericardial tap was not done. The patient improved dramatically coincident with return of prothrombic activity toward normal on the seventeenth hospital day. By the nineteenth hospital day the temperature and pulse had returned to normal and the friction rub had disappeared. Thereafter the clinical course was uneventful. The patient was discharged on the forty-second hospital day.

COMMENT

A review of the literature reveals that all reported cases of hemopericardium complicating myocardial infarction were due to rupture of the myocardium or of a coronary vessel. A review of the autopsy records at the Beth Israel Hospital of 160 cases of acute myocardial infarction without bishydroxycoumarin therapy similarly showed the occurrence of hemopericardium only when myocardial rupture was present. Although petechiae and injection of the epicardium were not infrequently noted and in 19 cases slightly blood-tinged pericardial fluid was found, frank gross hemorrhage into the pericardial cavity without rupture was noted only in the bishydroxycoumarin-treated patients. The conclusion appears warranted that in these cases bishydroxycoumarin was at least partly responsible for the hemopericardium.

Bishydroxycoumarin has two recognized physiological effects: 1. It interferes with the formation of prothrombin by the liver, resulting in a decreased concentration of prothrombin in the blood [6] and thereby causing a decrease in the production of the serum prothrombin conversion accelerator reported by Alexander and his associates [7] and a prolongation of the clotting time, as measured in siliconized equipment.[8] 2. In moderate to large doses it causes dilation of capillaries, small arteries and veins.[9] Except in the event of massive doses, which cause death within a few hours without any previous demonstrable effect upon prothrombin activity or the previously described thrombus. All vessels distal to this point were injected by the mass from the left coronary artery. Microscopic sections revealed both a healing and a fresh infarct in the areas of gross change noted above; the latter appeared to be of about 24 hours' duration.

On gross examination, the liver appeared slightly firmer than normal and there was congestion of the central veins. Microscopic examination revealed early acute central necrosis. Gross and microscopic examination of the kidneys and other organs revealed no abnormalities.

Case 2.—A 66 year old white woman was admitted to the hospital after an episode of chest pain. There was a 25 year history of moderately severe bronchial asthma and at least a 10 year history of hypertension; she had had albuminuria six years prior to the attack. Forty-eight hours before admission, substernal and left chest pain occurred suddenly. The pain was cutting in character and nonradiating. It lasted approximately two hours and was associated with sweating and vomiting. It was relieved by morphine and thereafter did not recur.

On admission, examination revealed an obese white woman who was moderately dyspneic and slightly cyanotic. Respirations were wheezing. The blood pressure was 180/100. The heart was moderately enlarged to the left. The rhythm was regular, with an occasional premature beat. The heart sounds were masked by the wheezing respiration. The anteroposterior diameter of the thorax was increased. There were loud ronchi and wheezes throughout both lung fields. The liver was felt 2 fingerbreadths below the right costal margin but was not tender. There was no icterus or edema. The white blood cell count was 43,400 (polymorphonuclear cells 79 per cent, band forms 6 per cent, lymphocytes 6 per cent and monocytes 8 per cent) and remained elevated during the entire period of hospitalization. There were no abnormal cells in the peripheral blood smear. The urine contained albumin (4 +) and 8 to 10 white blood cells per high power field in an uncatheterized specimen. The specific gravity ranged from 1.010 to 1.020. The electrocardiogram was characteristic of posterior myocardial infarction and complete auriculoventricular block.

Table 2.—*Prothrombic Response to Therapy*

Therapy consisted of bed rest and administration of oxygen, codeine, penicillin, potassium iodide and small doses of epinephrine (adrenalin®) in oil. Bishydroxycoumarin, 300 mg., was administered on the evening of admission. Within 36 hours of this single dose, the plasma prothrombic activity had fallen to 4 per cent as determined by the Rosenfield and Tuft technique [4] and, except for a single determination of 40 per cent on the fifth hospital day, remained below 5 per cent for the duration of hospitalization, despite the administration of only one additional dose of 50 mg. of bishydroxycoumarin on the fifth hospital day (table 2). Whether the finding of 40 per cent prothrombic activity on the fifth hospital day was a laboratory error, a response to the small dose of menadione sodium bisulfite (4.8 mg.) given on the previous day, or a representation of the wide fluctuations in prothrombic activity not infrequently observed, cannot be stated.

The temperature fell from a level of 101 F. to normal within 24 hours and remained there. The pulse rate ranged between 45 and 60, as the complete auriculoventricular block persisted. There was evidence of moderate renal insufficiency, with nonprotein nitrogen values ranging from 50 to 60 mg. per 100 cc., and was 54 mg. seven hours before the patient's death.

The asthma was easily controlled, and only small doses of epinephrine in oil were necessary (0.3 cc. of a 1: 500 suspension) on the first, second and fifth hospital days. The heart sounds, which on the first day were obscured by the respiratory wheezes, were of poor quality. At no time was a pericardial friction rub heard. On the eighth hospital day the patient became lethargic and there was a marked decrease in urinary output. These symptoms persisted despite intravenous administration of fluids. On the eleventh hospital day the patient complained of severe periumbilical pain, but there were no abnormal abdominal signs. The white blood cell count, which had gradually fallen from a level of 43,400 on admission to 13,000 on the tenth hospital day, rose to 33,800. Peripheral vascular collapse occurred shortly after the onset of pain. Within a few hours the blood pressure, previously maintained at a level of 130/80, was unobtainable. The patient failed to respond to therapy and died on the eleventh hospital day.

Postmortem Examination.—The pericardial cavity was almost completely obliterated by numerous dense fibrous adhesions. The pericardium was separated with great difficulty, and in several areas over the anterior surface the epicardial and parietal layers were so densely adherent that they were removed together from the myocardium. In a few areas posteriorly, where free pericardial space still persisted, there was an accumulation of 50 to 75 cc. of bloody fluid, and when this was removed a partially organized blood clot on the epicardium was noted. Careful examination revealed no evidence of rupture, tear or perforation of the myocardium or coronary vessels.

The heart weighed 470 Gm. On gross examination there was evidence of an extensive myocardial infarct involving the posterior wall of the left ventricle, the posterior portion of the interventricular septum and the posterior papillary muscle. Microscopic examination revealed massive infarction involving the posterior wall of the left and right ventricles, the interventricular septum, the posterior papillary muscle and the left atrium. The right ventricular extension of the infarct was recent and appeared to be less than 24 hours old. In this area of recent infarction several small veins contained fibrin thrombi. The epicardium was covered by a heavy layer of fibrin, which in some areas was overlaid with masses of red blood cells. The inner portion of the epicardium showed organization of the fibrinous exudate. With the exception of the uterus, no other area of hemorrhage was observed. The uterine cavity contained 2 to 3 cc. of bloody fluid. The endometrium was hemorrhagic. The serosal surface of the uterus was normal.

The pancreas appeared normal on gross examination, but the microscopic sections revealed evidence of acute and chronic pancreatitis and acute focal necrosis.

The kidneys were somewhat smaller than average. The right kidney weighed 110 Gm. and the left 130 Gm. There was some thinning of the cortex. Microscopic examination revealed that the renal substance was essentially preserved. There were moderate sclerosis of the interlobular vessel and some focal areas of scarring and tubular atrophy.

The remainder of the examination revealed no significant abnormalities.

The third patient with myocardial infarction and complicating pericarditis herein reported was admitted to the Beth Israel Hospital for the first time shortly after the first patient died. Bishydroxycoumarin therapy was instituted upon admission. The clinical features so closely resembled those of the first case that the diagnosis of hemorrhagic pericarditis appeared likely, although final proof is lacking, since the patient recovered and a pericardial tap was not done.

Case 3.—A 48 year old white man was hospitalized for recurrent chest pain of four days' duration. There was no history of rheumatic fever, hypertension or diabetes. For four years prior to admission he had noted mild anterior chest pain on moderate exertion. Four days prior to admission he experienced pain between the shoulder blades; it had come on suddenly and was aggravated by deep inspiration. Later that day, severe epigastric and anterior chest pain developed and was associated with a feeling of weakness in both arms and legs. Three days prior to admission, the temperature was 103 F. The heart sounds were poor, the patient was cyanotic, and signs consistent with consolidation at the base of the left lung were noted. An electrocardiogram showed changes characteristic of an extensive anterior myocardial infarct (fig. 2).

Examination on his admission to the hospital two days later revealed an acutely ill man with slight cyanosis; the respiratory rate was 25, temperature 103 F., pulse rate 100, and regular, and blood pressure 100/80. There was no engorgement of the neck veins. The heart was enlarged to the anterior axillary line, and a loud to and fro friction rub masked the heart sounds. There was bronchial breathing at the base of the left lung and diminished breath sounds and moist rales at the base of the right lung. The abdominal examination was noncontributory, and there was no peripheral edema. The white blood cell count was 16,000 per cubic millimeter. The sedimentation rate was 2.2 mm. per minute (Rourke-Ernstene method [3]). The urine was normal. The nonprotein nitrogen was 40 mg. per 100 cc. Therapy consisted of bed rest, liquid diet, fluids up to 2,500 cc., meperidine hydrochloride, as necessary, for pain, oxygen and bishydroxycoumarin. The prothrombic activity was maintained generally between 10 to 20 per cent of normal as estimated by the Rosenfield and Tuft technique [4] (prothrombin time between 20 and 30 seconds) (table 3).

During the first 12 hospital days, the patient showed clinical improvement. The temperature fell slowly, reaching normal by the seventh day, and the pulse rate during this period fell from 100 to 70. The chest pain necessitated frequent medication at first but was not troublesome after 72 hours. The cyanosis disappeared within 48 hours, and the use of oxygen was discontinued on the fourth hospital day. The blood pressure was maintained at 100-110/70-80. The friction rub disappeared after the first 24 hours but returned on the fifth day and persisted with varying intensity during and following the first period of clinical improvement.

On the afternoon of the thirteenth hospital day, there was a recurrence of anterior chest pain with cyanosis, weakness and profuse sweating. There was no change in the blood pressure, but there was a rise in the heart rate and the friction rub was louder than was previously noted. It was felt that the recurrence and persistence of the friction rub might be secondary to oozing of blood from the inflamed pericardial surfaces and that the sudden deterioration in the patient's condition conceivably was due to profuse bleeding into the pericardial sac. The use of bishydroxycoumarin was discontinued, and 72 mg. of menadione sodium bisulfite was given intravenously on the thirteenth and fourteenth days (table 3). On the fifteenth day the temperature rose to 102 F., the pulse rate to 110 and the respiration rate to 25. Repeated electrocardiograms showed no evidence of fresh infarction. A chest film revealed an increase in heart size when compared with a film taken shortly after admission. These findings were consistent with, but not clearly diagnostic of, pericardial effusion. However, inasmuch as there was no evidence of cardiac tamponade, pericardial tap was not done. The patient improved dramatically coincident with return of prothrombic activity toward normal on the seventeenth hospital day. By the nineteenth hospital day the temperature and pulse had returned to normal and the friction rub had disappeared. Thereafter the clinical course was uneventful. The patient was discharged on the forty-second hospital day.

COMMENT

A review of the literature reveals that all reported cases of hemopericardium complicating myocardial infarction were due to rupture of the myocardium or of a coronary vessel. A review of the autopsy records at the Beth Israel Hospital of 160 cases of acute myocardial infarction without bishydroxycoumarin therapy similarly showed the occurrence of hemopericardium only when myocardial rupture was present. Although petechiae and injection of the epicardium were not infrequently noted and in 19 cases slightly blood-tinged pericardial fluid was found, frank gross hemorrhage into the pericardial cavity without rupture was noted only in the bishydroxycoumarin-treated patients. The conclusion appears warranted that in these cases bishydroxycoumarin was at least partly responsible for the hemopericardium.

Bishydroxycoumarin has two recognized physiological effects: 1. It interferes with the formation of prothrombin by the liver, resulting in a decreased concentration of prothrombin in the blood [6] and thereby causing a decrease in the production of the serum prothrombin conversion accelerator reported by Alexander and his associates [7] and a prolongation of the clotting time, as measured in siliconized equipment.[8] 2. In moderate to large doses it causes dilation of capillaries, small arteries and veins.[9] Except in the event of massive doses, which cause death within a few hours without any previous demonstrable effect upon prothrombin activity or the appearance of hemorrhagic phenomena,[2c,d] all the toxic signs and symptoms and the parenchymatous changes that have been reported are secondary to hemorrhage resulting from the hypoprothrombinemia and vasodilatation. In animal experiments [10] and in cases of bishydroxycoumarin poisoning,[11] when the prothrombin is markedly reduced, extensive hemorrhage has been observed in every tissue and body cavity, including the pericardial space. Pericardial hemorrhage, however, has been noted only in the experiments reported by Quick,[12] and in the case reported by Duff and Shull.[13] In this connection the studies of Blumgart and others [2e] on the effect of bishydroxycoumarin on experimentally produced myocardial infarction in dogs is noteworthy. In these animals with myocardial infarction and surgically traumatized pericardium, marked hypoprothrombinemia was produced by the administration of this drug. Although other hemorrhagic phenomena occurred, there were no instances of bleeding into the pericardial sac. Quick [12] found that in rabbits, when the prothrombin time was less than 19 seconds (normal prothrombin time is 6 seconds), the animal's blood could prevent cardiac bleeding from a heart puncture. When the prothrombin time was 24 seconds or more, fatal hemopericardium invariably occurred. In the case of bishydroxycoumarin poisoning, with extensive hemorrhagic phenomena, reported by Duff and Shull,[11d] 40 cc. of serosanguineous fluid was present in the pericardial sac; there were petechiae in the right ventricle and right atrium, and a diffuse hematoma was present in the atrial wall.

[9] Rose and others.[2a] Richards and Cortell.[2c] *Bingham and others.*[2d] Dale, D. U., and Jaques, L. B.: The Prevention of Experimental Thrombosis by Dicumarin. Canad. M. A. J. **46**: 546 (June) 1942.

The reported complications of anticoagulant therapy in myocardial infarction when the prothrombin is kept at the "optimum" level have been limited to relatively mild hemorrhagic phenomena: epistaxis, hemoptysis, guaiac-positive stools, hematuria, purpura, hematomas and hemarthrosis.[14] It is noteworthy that no instances of hemopericardium in bishydroxycoumarin-treated patients with acute infarction have been reported. It is probable, however, that hemopericardium has been observed in such cases but that its significance has not been appreciated. In the presence of fibrinous pericarditis, a common complication of acute myocardial infarction, the constantly moving, vascular, granulating serous surface would appear to provide conditions that predispose to bleeding when severe hypoprothrombinemia and vasodilatation are produced by bishydroxycoumarin. However, the extensive adhesive pericarditis found in cases 1 and 2 suggests that the organization of the fibrin deposited from blood oozing into the pericardial space may result in widespread pericardial adhesions. This would tend to inhibit extensive hemorrhage and tamponade in most cases and may account for the infrequency of extensive hemopericardium.

The literature referred to [15] clearly indicates that the clotting defect produced by bishydroxycoumarin may itself result in pericardial hemorrhage even in the absence of antecedent pericarditis. Nevertheless, it should be noted that vascular collapse, icterus, congestive heart failure and renal insufficiency were present in our cases. Since these conditions predispose to hemorrhage, the possibility that they enhanced the tendency toward bleeding cannot be excluded. This consideration must not be overlooked when one is deciding whether or not a patient with acute myocardial infarction is to receive bishydroxycoumarin and what the dosage schedule is to be.

The unusual persistence of a pericardial friction rub in the proved case of hemorrhagic pericarditis (case 1) and in the one suspected case (case 3) suggests that a continual oozing of a small amount of blood from the involved pericardial surfaces may have occurred for days. This opinion is confirmed by the postmortem findings in the first case. The sudden change in the clinical course, as characterized by chest pain, fever, tachycardia, cyanosis, vascular collapse and venous distention in the presence of a persistent pericardial friction rub, suggests profuse hemorrhage into the pericardial space. This possibility was not suspected in the first case, and cardiac tamponade proved to be the immediate cause of death. The similar clinical course in the third case suggested pericardial hemorrhage, and the withdrawal of bishydroxycoumarin and the administration of menadione sodium bisulfite were followed by recovery. In the second case a friction rub was not heard and hemorrhagic pericarditis was not suspected. The occurrence of abdominal pain and shock were probably due either to the extension of the infarction or to the pancreatitis. The hemopericardium was not extensive enough to cause any cardiac embarrassment. The free pericardial space was almost obliterated.

When a pericardial friction rub is not audible, it may be impossible to make a diagnosis of pericardial hemorrhage, unless pericardial effusion, which is rare in uncomplicated acute myocardial infarction, can be demonstrated.

In case 1, the pronounced rise of the prothrombin time after the use of bishydroxycoumarin had been discontinued occurred when the patient was in shock and may have been due to the impairment of liver function secondary to congestion and shock.[16] The unusual response to a small dose of bishydroxycoumarin in the second case was probably related to impaired renal function. It has been shown experimentally that a decrease in renal function results in enhancement and prolongation of the hypoprothrombic effect of bishydroxycoumarin.[16]

It should be noted that the prothrombin times and prothrombic activities in the third case were well within the recommended therapeutic ranges when the suspected bleeding occurred. In a previous communication by Alexander, de Vries and one of us (R. G.)[17] the methods of prothrombin determination and their clinical significance have been critically evaluated. It was pointed out that wide fluctuations of prothrombin concentration may occur (cases 2 and 3) in patients receiving bishydroxycoumarin.

The discontinuance of bishydroxycoumarin therapy and the intravenous administration of large amounts of vitamin K have been shown to have little effect upon the prothrombin level for at least 10 to 12 hours[18] and may not result in normal levels for several days. (More recently, vitamin K_1 oxide has been demonstrated to be much more effective than other preparations in bishydroxycoumarin-produced hypoprothrombinemia.[19] Although such treatment may suffice when there is only slight oozing into the pericardial sac, when more profuse bleeding occurs transfusion of blood or plasma is indicated to correct the deficiency in prothrombin. Transfusions have a temporary effect and should be repeated until the normal mechanism for the production of prothrombin, stimulated by the administration of vitamin K, can maintain satisfactory levels of prothrombin. The course of treatment can best be guided by frequent determinations of the prothrombin time. If cardiac tamponade develops, a pericardial tap should be done. It is important that the prothrombic activity of the blood be kept close to normal levels after such a procedure in order to avoid bleeding secondary to the procedure.

SUMMARY AND CONCLUSIONS

Hemopericardium has been observed during the course of bishydroxycoumarin therapy for acute myocardial infarction. Two cases of proved and one of suspected hemopericardium are reported.[20] Cardiac tamponade was the immediate cause of death in one of the patients.

The diagnosis of hemorrhagic pericarditis should be suspected in the presence of (1) a prolonged and persistent or recurrent friction rub, (2) recurrence of cardiac pain, (3) vascular collapse accompanied with distended neck veins and (4) demonstration of pericardial effusion. The continuation of bishydroxycoumarin therapy in case of myocardial infarction with persistent pericardial friction rub may be hazardous.

Bishydroxycoumarin, by causing severe depression of prothrombic activity and vascular dilatation, predisposes one to hemorrhage, of which a potent source is found in the constantly moving granulating serous surfaces of the inflamed pericardium. Furthermore, multiple factors that interfere with hemostasis are commonly present in acute myocardial infarction, and these must be evaluated before bishydroxycoumarin is administered or the dosage schedule is decided on. The necessity for rigid control of bishydroxycoumarin therapy is emphasized.

Hemorrhage into the pericardium in bishydroxycoumarin-treated patients with acute myocardial infarction is an emergency, and every physician using the drug should be aware of the possibility of this serious complication.

The treatment of bishydroxycoumarin poisoning should include withdrawal of bishydroxycoumarin and should include the intravenous injection of vitamin K (preferably vitamin K_1 oxide) and the repeated transfusion of blood or plasma until the prothrombin time reaches normal levels and remains there. If cardiac tamponade develops, a pericardial tap should be done.

[20] Since the preparation of this manuscript, two more instances of hemorrhagic pericarditis occurring in bishydroxycoumarin-treated patients with acute myocardial infarction have been found at postmortem examination. There was no evidence of rupture of the myocardium or of any coronary vessels in either case.

HISTOPLASMOSIS, TUBERCULOSIS AND COCCIDIOIDOMYCOSIS

W. G. Beadenkopf, M.D.
and
Clayton G. Loosli, M.D., Chicago

The present concepts of histoplasmosis have resulted, in large part, from a more critical examination of disease processes that were formerly considered to be almost exclusively of tuberculous origin. Prior to 1945 the infrequent reports of cases of histoplasmosis suggested little association with tuberculosis aside from the pathological impression that each appeared, usually, as a chronic granulomatous infection. By 1945, however, evidence had accumulated for the existence of pulmonary calcifications demonstrated roentgenologically in a large number of persons, insensitive to tuberculin, who lived in middle western and contiguous states.[1] Furthermore, to add emphasis to the problem of such calcifications in this area, an analysis of draft board chest roentgenograms, reported in 1943 showed that the Middle West was the region of highest prevalence of this condition in the United States.[2] Such a geographic distribution did not correspond at all well with tuberculosis mortality.[3] Following the observations of Tager and Liebow,[4] and at the suggestion of Smith,[5] Christie and Peterson[6] and Palmer[7] were readily able to show that most patients with pulmonary calcification of this puzzling origin were not only sensitive to the antigen histoplasmin but also had spent most of their lives in middle western states.

Presented before a meeting of the Mississippi Valley Conference on Tuberculosis and the Mississippi Valley Trudeau Society at Columbus, Ohio, Sept. 22, 1950.

From the Preventive Medicine Section and the Student Health Service, Department of Medicine, University of Chicago. This investigation was supported (in part) by a research grant from the Division of Research Grants and Fellowships, National Institutes of Health, Public Health Service.

The postulate was thus implied that histoplasmosis was not a disease that was limited to a rare and fatal form but that it might be widespread and include, in addition to its fatal form, a range of mild pulmonary infections that would frequently result in lung calcifications. A parallelism with tuberculosis was thus established.

The infection that is defined as histoplasmosis is caused by the fungus Histoplasma capsulatum. The organism was proved a cultivable fungus by DeMonbreun in 1934.[8] A specific antigen was extracted from broth filtrates of cultures, in 1941, by two groups of investigators,[9] and the material became employed as a skin-testing antigen in a manner similar to that in which tuberculin is used. This antigen, histoplasmin, has proved invaluable in delineating the Lower Mississippi Basin as the endemic area for histoplasmosis and in suggesting other endemic areas outside the United States. Histoplasmin has also been of value in distinguishing between tuberculous and histoplasmotic infections in patients with pulmonary calcification or infiltrates.

EPIDEMIOLOGY

The area endemic for the disease in the United States has been studied by many interested groups during the past five years. Although the mode of infection is still far from clear, there are important epidemiological aspects of histoplasmosis that are known today, aspects which will probably mark out the direction of future, more conclusive work.

As a result of histoplasmin skin-testing surveys,[10] a degree of infection is indicated to exist among the residents of the Mississippi Valley that frequently exceeds 50 per cent. In fact, in certain counties of Illinois, young adult women and men have shown rates of sensitivity above 95 per cent.[11] The Mississippi Basin regionalization of histoplasmosis is distinctly unlike the geographic distribution of tuberculosis, as illustrated by mortality rates [3] or tuberculin sensitivity rates.[12] Such a type of regionalization as that which exists for histoplasmosis corresponds exceedingly well, however, with the geographic distribution of pulmonary calcifications,[13] as previously indicated.

A high rate of infection has been attained within this endemic area usually by the time of adolescence. Infants have shown negligible rates of sensitivity, but during the first decade of life substantial rates have been found of approximately 40 to 60 per cent,[14] depending on the local area. Women have been found, in general, to have slightly lower rates of infection than do men.[15] Negroes have been found to have approximately the same infection rate [12a] or a rate slightly lower [10c] than that for whites. This racial similarity of the histoplasmin rates is significantly unlike the great racial difference in tuberculin sensitivity rates and suggests that economic factors are not so important in the acquisition of a H. capsulatum infection. Also, unlike tuberculosis, the histoplasmosis infection rate for urban residents is not higher than that for rural dwellers. Indeed, an indication of higher rural rates has been reported for Ohio.[10d]

The practical point of whether histoplasmosis is communicable from person to person is not settled. However, the indications at present are that this disease is not generally so transmitted. Family studies of Kansas City residents showed only slight indication that, if one child of a family were infected, his siblings would be more likely than not to be infected.[16] Such evidence against interpersonal infection stands in sharp contrast to the results of comparable studies of tuberculosis by Opie, McPhedran and their associates.[17] Evidence that families are not usually attacked as units by the H. capsulatum fungus indicates also that the dissemination of histoplasmosis has little in common with the mode of spread of several other classes of disease that usually attack family units or small groups: sputum-disseminated diseases other than tuberculosis, the milk-borne, meat-borne and the usual pet-borne and rodent-borne diseases. During recent months a fatality from histoplasmosis was reported in Decatur, Ill.,[18] that occurred in a 5 month old identical twin girl. Though kept in the same crib with the ill sister during the first two weeks of a four week illness, the surviving twin girl had no detectable illness, did not react to histoplasmin and is well today. However, this episode cannot be considered convincing, by virtue of the absence of any open lesion on the body surface of the sick baby and little or no pulmonary involvement.

Additional indications against interpersonal infection by the H. capsulatum fungus exist in the geographic distribution of infected populations. If family units formed foci for infection, as they have been shown to do for tuberculosis,[17] there would be expected a more spotty and less regionalized endemic area. For tuberculosis a more spotty geographic distribution does exist, though

it may be attributed, in part, to more intensive case reporting.[3] However, for histoplasmosis the distribution is strikingly regionalized, in a manner similar to the regionalization of coccidioidomycosis in the San Joaquin Valley of California.[5] For this reason histoplasmosis might be expected to be spread, like coccidioidomycosis. Indeed, we have recently suggested [11] a possible method of natural infection by H. capsulatum that, in brief, consists of: (*a*) dissemination of the soil-fungus mixture by floods in the Mississippi Valley, and (*b*) after drying, a further dissemination of the dried mixture by winds, resulting in air-borne infection.

Evidence from observations of both animal and human infections with the fungus is being accumulated to show that, within certain limits, which are discussed below, a positive histoplasmin skin test means a past or present histoplasmotic infection. In this way, the test resembles the tuberculin skin test used at diagnostic strengths.[19] There is resemblance, also, in the fact that critical illnesses resulting from several causes, old age—and, particularly, both factors in combination — depress sensitivity to both histoplasmin and tuberculin.[20] The histoplasmin skin test has certain limitations in specificity in the presence of infection by two other fungi, Coccidioides and Blastomyces,[21] apparently due to cross sensitivity with these fungi.[22] Both histoplasmin and tuberculin skin tests appear relatively independent and specific, however, each in the presence of infection by the other organism. Chinese students at the University of Chicago who reacted to tuberculin almost 100 per cent showed a negligible reaction rate to histoplasmin.[12a] Residents of certain Illinois counties who reacted to histoplasmin almost 100 per cent likewise showed a negligible reaction rate to tuberculin.[11] Some association between tuberculin and histoplasmin tests has been found among student nurses in certain cities of the United States, but this association is slight and, even if due to cross sensitivity, would seldom confuse diagnostic procedures.[23]

SYMPTOMATOLOGY

It may be possible in the future to predict with accuracy the probabilities of various disease processes and symptom patterns that can be expected after an infective dose of H. capsulatum. If interpersonal exchange of the disease continues to be unlikely or rare, such a prediction in the form of a spectrum of the disease should be as attainable as that excellent picture of coccidioidomycosis symptomatology that was worked out by Smith and his associates [24] during the recent war.

An attempt today to construct a disease spectrum for histoplasmosis must be extremely tentative and offered only with the understanding that changes of generous proportions will not only be required later, but perhaps even at present will be insisted on by others in the field. Clinical reports are appearing in increasing frequency today describing a wide variety of infections that, altogether, make any general description of the disease uncertain. Furthermore, the whole gamut of illness severity, from a symptomless infection to a rapidly fatal generalized infection, seems to characterize histoplasmosis.

The first and mildest portion of a spectrum, the symptomless infection, grossly defined as it is in a medical history as "no previous significant illness," appears to occur in the majority of persons after infection by the fungus. Attempts to detect illness have generally been unsuccessful even among students who have been observed to develop histoplasmin sensitivity, i. e., to convert from a nonreactor to a reactor within a period of months.[25] Some assistance in identifying the disease process in this type of infection has been obtained with information from serial complement fixation determinations, which employ the mycelian phase antigen,[26] the yeast phase antigen [27] and the collodion agglutination test.[28] Suggestions of activity, obtained serologically, have intensified cultural search and search for specific organ lesions and functional abnormalities. However, the principal means of identifying the asymptomatic infection has been until now the positive skin test reaction, and it has represented the only sign of disease in the majority of infected persons.

The second portion of the spectrum appears to be the frequently encountered pulmonary infection. The calcified lesion that appears in chest roentgenograms has been demonstrated usually in over one fourth of adults infected with H. capsulatum.[29] Many of this group has no illness apparent to them and symptomatically could be placed in the first portion of the disease spectrum. However, there is an increasing number of reports describing various types of chronic pulmonary infiltrates, with and without cavitation, that are either proved to be

histoplasmosis or that display strong suggestion of the diseases.[30] Like tuberculosis, the infiltrates are found to occur, frequently, without symptoms. In some of the cases reported, the complement fixation test has proved to be of considerable value in distinguishing the causes of these pulmonary infiltrates that roentgenologically could be considered due to either tuberculosis or histoplasmosis. Sputum cultures that show the fungus have supplied final proof.

Pulmonary infiltrates encountered in student nurses who react to histoplasmin and in those who react to tuberculin were compared by Edwards, Lewis and Palmer.[30f] There was a tendency described among the histoplasmin reactors, which has also been found by others [31] to have a nodular type of infiltrate located in almost any area of the lung fields, in contrast to the tendency of the tuberculin reactors to have softer infiltrates, located more toward the apexes. Mediastinal lymphadenopathy was found to accompany the infiltrates of the histoplasmin reactors more frequently than it did the infiltrates of the tuberculin reactors.

Recent reports have shown the H. capsulatum fungus to be responsible for acute pulmonary infiltrates that occurred in association with both generalized and chest symptoms.[30d,h] Such reports suggest histoplasmosis as the cause of some of the atypical pneumonia type of illnesses.

Many of the pulmonary infiltrates, both acute and chronic, which have been demonstrated and considered to be histoplasmosis, can be expected to develop calcified bodies in the lung fields. Some cases have been followed for several years, and the development of calcification has been demonstrated.[32] On the other hand, some portion of the pulmonary infections probably clears up entirely, as indicated roentgenologically, and the patients retain only skin sensitivity as evidence of their infections.

The third portion of the spectrum of symptoms is the infection not involving the lungs primarily. Reports have described nonfatal infections in a variety of locations: the skin, mouth, tongue,[33] larynx,[30d] penis [33] and several structures in the eye,[34] to mention some of the locations. An estimate of the proportion represented by this varied group in the general disease spectrum is not possible, and it may prove inaccurate to estimate the number as less than that of pulmonary infections.

Closely associated with the nonpulmonary type of infections are the nonfatal generalized infections that have been reported.[35] This type, by virtue of the generalized infection, also resembles the final portion of the spectrum, the fatal generalized infection, in that it frequently shows involvement of the lymph nodes, liver and spleen, as manifested by enlargement of these organs. The severity of these general infections has varied from an asymptomatic infection to a critical illness. Pulmonary infiltrates have frequently accompanied the general infections. As Saslaw and Campbell have pointed out,[28b] serial serological examinations could be of considerable assistance in identifying the general infection and may prove of value in promoting the identification of some cases of "fever of unknown origin."

The final, fourth portion of the disease spectrum, probably infecting the smallest number of persons, is the fatal generalized infection. This form includes most of the rarely detected cases of histoplasmosis recorded prior to 1945.[36] Some of these infections are exceedingly rapid in their course, especially in infants, with death occurring as rapidly as within several weeks after the onset of symptoms.[37] In adults, however, the duration of illness extends usually for periods of months to several years. One phase of the fatal form consists of the H. capsulatum infection that runs concomitantly with a second, usually earlier diagnosed, disease. Tuberculosis,[30d] lymphoma [36] and other diseases have been found in combination with histoplasmosis.

A parallelism between histoplasmosis and coccidioidomycosis has been pointed out by others.[38] Some clinical dissimilarities between the diseases persist at this time, however: (*a*) the rarity or absence of erythema nodosum and bone lesions with histoplasmosis, in contrast to their occurrence with coccidioidomycosis, and (*b*) the presence of gastrointestinal ulcerations with histoplasmosis in contrast to their absence in coccidioidomycosis.[39]

SUMMARY

In this discussion the similarities and dissimilarities in the epidemiology and disease characteristics of histoplasmosis, tuberculosis and coccidioidomycosis have been given. In general, these diseases present many similarities. Each affects many persons, without detectable signs or symptoms beyond skin sensitivity development; each is prone to attack the lungs, producing either acute or chronic infiltrates that are known to be frequently indistinguishable roentgenologically, and each has a relatively uncommon form consisting of a fatal disseminated infection. No comparative data concerning the course and fatality rates of the three types of infection are available. Although there are certain fundamental differences in the epidemiology of histoplasmosis, tuberculosis and coccidioidomycosis, the above similarities are of such importance that all three diseases should be considered in any tuberculosis control program.

SUCTION SOCKET

PROPER SELECTION OF PATIENTS FOR ABOVE KNEE ARTIFICIAL LEG

Charles O. Bechtol, M.D., Oakland, Calif.

The purpose of this paper is to present facts of clinical importance in the prescription and fitting of the suction socket above knee artificial leg. The suction socket has been shown to be advantageous as a fittting method for most above knee amputees. The actual fitting and alignment of a section socket leg involves special problems of functional anatomy and gait.[1] Excellent historical, statistical and technical reviews are available on the suction socket method of fitting, and these aspects of the problem will not be discussed in this paper.[2] Four subjects of clinical importance will be discussed: (1) the time required for the fitting of the suction socket, (2) the types of stumps in which difficult fit may be expected, (3) the type of surgical technique in amputation which produces a stump most favorable for fitting the suction socket and (4) the postoperative care and preparation for the fitting of a suction socket.

TIME REQUIRED FOR FITTING OF THE SUCTION SOCKET

The fitting of a suction socket above knee prosthesis is time consuming because the suction socket requires a more accurate fit than the conventional type of prosthesis. Suction is maintained by an accurate fit. Weight bearing on the ischial seat is comfortable only if this seat is accurately placed. Since the bony and muscular anatomy is quite variable from one stump to another, there is no single standard socket pattern suitable for all amputees.

In contrast to the atrophy and shrinkage of muscle encountered with the use of the belt type of leg, the muscles usually become hypertrophied and firm with the use of the suction socket leg. This necessitates enlarging of the socket, since, if the socket is not enlarged, a severe edema of the end of the stump will occur. Some sockets have been enlarged from 10 to 20 times during the first year or two of wear. This is particularly common in stumps in which the musculature is very flabby at the time of initial fitting.

Because of the added fitting time and the necessary returns to the limb shop for enlargement of the socket, the suction socket should not be recommended for any patient who cannot spare this additional time. This should be thoroughly explained to any patient who lives at a distance from the limb dealer or whose business commitments might interfere with frequent returns for fittings. Patients who are uncooperative or who are irresponsible should likewise be discouraged from choosing the suction socket.

TYPES OF STUMPS WHICH ARE DIFFICULT TO FIT

Almost any type of stump can be fitted, provided the amputee is cooperative and willing to return for the necessary fittings. In some difficult stumps it has taken a year or more to finally achieve a satisfactory fit. Those who have rejected the suction socket, on the other hand, have almost never done so on the basis of fitting difficulties alone. Rejection of the suction socket is almost always a combination of the factors of difficulty in fitting, plus the fact that the patient is unable to return at frequent intervals for revisions of the shape of the socket. Therefore, if any of the stump conditions mentioned below are present, the amputee should be specifically warned that his fitting will be slower than usual and that *he may expect to return many times for revisions of the* shape of the socket.

Flabby stumps are both difficult to fit and require frequent enlargement of the socket during the initial period of fit. A flabby stump may be due either to atrophic muscle or excessive subcutaneous fat or both. This type of stump allows marked rotation of the soft tissues even when the muscles are tensed. The stump should be tested by grasping it firmly with both hands and rotating the soft tissues to the left and right, first with the stump muscles relaxed, and then with the stump tensed. A rotation which allows the skin to move more than 2 or 3 inches (5 or 7.6 cm.) in either direction indicates that some difficulty in fitting may be expected. If the rotation can be carried out through approximately 90 degrees, a very marked amount of stump growth will undoubtedly follow the use of the suction socket, and the patient should be warned that he will have to return many times for enlargement of the socket.

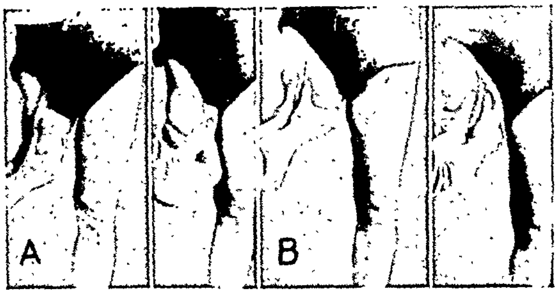

Fig. 1.—Test for firmness of the stump and degree of soft tissue rotation. *A*, a flabby stump, showing marked degree of soft tissue rotation. This occurs even though the muscles are tensed. *B*, a firm stump, showing little rotation.

histoplasmosis or that display strong suggestion of the diseases.[30] Like tuberculosis, the infiltrates are found to occur, frequently, without symptoms. In some of the cases reported, the complement fixation test has proved to be of considerable value in distinguishing the causes of these pulmonary infiltrates that roentgenologically could be considered due to either tuberculosis or histoplasmosis. Sputum cultures that show the fungus have supplied final proof.

Pulmonary infiltrates encountered in student nurses who react to histoplasmin and in those who react to tuberculin were compared by Edwards, Lewis and Palmer.[30f] There was a tendency described among the histoplasmin reactors, which has also been found by others [31] to have a nodular type of infiltrate located in almost any area of the lung fields, in contrast to the tendency of the tuberculin reactors to have softer infiltrates, located more toward the apexes. Mediastinal lymphadenopathy was found to accompany the infiltrates of the histoplasmin reactors more frequently than it did the infiltrates of the tuberculin reactors.

Recent reports have shown the H. capsulatum fungus to be responsible for acute pulmonary infiltrates that occurred in association with both generalized and chest symptoms.[30d,h] Such reports suggest histoplasmosis as the cause of some of the atypical pneumonia type of illnesses.

Many of the pulmonary infiltrates, both acute and chronic, which have been demonstrated and considered to be histoplasmosis, can be expected to develop calcified bodies in the lung fields. Some cases have been followed for several years, and the development of calcification has been demonstrated.[32] On the other hand, some portion of the pulmonary infections probably clears up entirely, as indicated roentgenologically, and the patients retain only skin sensitivity as evidence of their infections.

The third portion of the spectrum of symptoms is the infection not involving the lungs primarily. Reports have described nonfatal infections in a variety of locations: the skin, mouth, tongue,[33] larynx,[30d] penis [33] and several structures in the eye,[34] to mention some of the locations. An estimate of the proportion represented by this varied group in the general disease spectrum is not possible, and it may prove inaccurate to estimate the number as less than that of pulmonary infections.

Closely associated with the nonpulmonary type of infections are the nonfatal generalized infections that have been reported.[35] This type, by virtue of the generalized infection, also resembles the final portion of the spectrum, the fatal generalized infection, in that it frequently shows involvement of the lymph nodes, liver and spleen, as manifested by enlargement of these organs. The severity of these general infections has varied from an asymptomatic infection to a critical illness. Pulmonary infiltrates have frequently accompanied the general infections. As Saslaw and Campbell have pointed out,[28b] serial serological examinations could be of considerable assistance in identifying the general infection and may prove of value in promoting the identification of some cases of "fever of unknown origin."

The final, fourth portion of the disease spectrum, probably infecting the smallest number of persons, is the fatal generalized infection. This form includes most of the rarely detected cases of histoplasmosis recorded prior to 1945.[36] Some of these infections are exceedingly rapid in their course, especially in infants, with death occurring as rapidly as within several weeks after the onset of symptoms.[37] In adults, however, the duration of illness extends usually for periods of months to several years. One phase of the fatal form consists of the H. capsulatum infection that runs concomitantly with a second, usually earlier diagnosed, disease. Tuberculosis,[30d] lymphoma [36] and other diseases have been found in combination with histoplasmosis.

A parallelism between histoplasmosis and coccidioidomycosis has been pointed out by others.[38] Some clinical dissimilarities between the diseases persist at this time, however: (*a*) the rarity or absence of erythema nodosum and bone lesions with histoplasmosis, in contrast to their occurrence with coccidioidomycosis, and (*b*) the presence of gastrointestinal ulcerations with histoplasmosis in contrast to their absence in coccidioidomycosis.[39]

SUMMARY

In this discussion the similarities and dissimilarities in the epidemiology and disease characteristics of histoplasmosis, tuberculosis and coccidioidomycosis have been given. In general, these diseases present many similarities. Each affects many persons, without detectable signs or symptoms beyond skin sensitivity development; each is prone to attack the lungs, producing either acute or chronic infiltrates that are known to be frequently indistinguishable roentgenologically, and each has a relatively uncommon form consisting of a fatal disseminated infection. No comparative data concerning the course and fatality rates of the three types of infection are available. Although there are certain fundamental differences in the epidemiology of histoplasmosis, tuberculosis and coccidioidomycosis, the above similarities are of such importance that all three diseases should be considered in any tuberculosis control program.

SUCTION SOCKET

PROPER SELECTION OF PATIENTS FOR ABOVE KNEE ARTIFICIAL LEG

Charles O. Bechtol, M.D., Oakland, Calif.

The purpose of this paper is to present facts of clinical importance in the prescription and fitting of the suction socket above knee artificial leg. The suction socket has been shown to be advantageous as a fittting method for most above knee amputees. The actual fitting and alignment of a section socket leg involves special problems of functional anatomy and gait.[1] Excellent historical, statistical and technical reviews are available on the suction socket method of fitting, and these aspects of the problem will not be discussed in this paper.[2] Four subjects of clinical importance will be discussed: (1) the time required for the fitting of the suction socket, (2) the types of stumps in which difficult fit may be expected, (3) the type of surgical technique in amputation which produces a stump most favorable for fitting the suction socket and (4) the postoperative care and preparation for the fitting of a suction socket.

TIME REQUIRED FOR FITTING OF THE SUCTION SOCKET

The fitting of a suction socket above knee prosthesis is time consuming because the suction socket requires a more accurate fit than the conventional type of prosthesis. Suction is maintained by an accurate fit. Weight bearing on the ischial seat is comfortable only if this seat is accurately placed. Since the bony and muscular anatomy is quite variable from one stump to another, there is no single standard socket pattern suitable for all amputees.

In contrast to the atrophy and shrinkage of muscle encountered with the use of the belt type of leg, the muscles usually become hypertrophied and firm with the use of the suction socket leg. This necessitates enlarging of the socket, since, if the socket is not enlarged, a severe edema of the end of the stump will occur. Some sockets have been enlarged from 10 to 20 times during the first year or two of wear. This is particularly common in stumps in which the musculature is very flabby at the time of initial fitting.

Because of the added fitting time and the necessary returns to the limb shop for enlargement of the socket, the suction socket should not be recommended for any patient who cannot spare this additional time. This should be thoroughly explained to any patient who lives at a distance from the limb dealer or whose business commitments might interfere with frequent returns for fittings. Patients who are uncooperative or who are irresponsible should likewise be discouraged from choosing the suction socket.

TYPES OF STUMPS WHICH ARE DIFFICULT TO FIT

Almost any type of stump can be fitted, provided the amputee is cooperative and willing to return for the necessary fittings. In some difficult stumps it has taken a year or more to finally achieve a satisfactory fit. Those who have rejected the suction socket, on the other hand, have almost never done so on the basis of fitting difficulties alone. Rejection of the suction socket is almost always a combination of the factors of difficulty in fitting, plus the fact that the patient is unable to return at frequent intervals for revisions of the shape of the socket. Therefore, if any of the stump conditions mentioned below are present, the amputee should be specifically warned that his fitting will be slower than usual and that he may expect to return many times for revisions of the shape of the socket.

Flabby stumps are both difficult to fit and require frequent enlargement of the socket during the initial period of fit. A flabby stump may be due either to atrophic muscle or excessive subcutaneous fat or both. This type of stump allows marked rotation of the soft tissues even when the muscles are tensed. The stump should be tested by grasping it firmly with both hands and rotating the soft tissues to the left and right, first with the stump muscles relaxed, and then with the stump tensed. A rotation which allows the skin to move more than 2 or 3 inches (5 or 7.6 cm.) in either direction indicates that some difficulty in fitting may be expected. If the rotation can be carried out through approximately 90 degrees, a very marked amount of stump growth will undoubtedly follow the use of the suction socket, and the patient should be warned that he will have to return many times for enlargement of the socket.

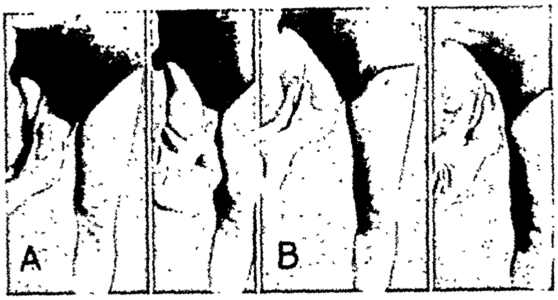

Fig. 1.—Test for firmness of the stump and degree of soft tissue rotation. *A*, a flabby stump, showing marked degree of soft tissue rotation. This occurs even though the muscles are tensed. *B*, a firm stump, showing little rotation.

Surgery **78**: 603-613 (Nov.) 1949.

Short stumps in which the femur measures less than 5 or 6 inches (12.7 or 15 cm.) from the top of the trochanter are difficult to fit. Though the fit may be satisfactory for walking, suction is frequently lost when sitting down or in getting in or out of an automobile. It must be emphasized, however, that the suction socket method of fitting offers particular advantages to short stumps because of the increased control and reduced piston action, and the amputee with a short stump should be discouraged only if he is unable to spend the necessary time for fitting.

Very long stumps resulting from the Callender or Gritti-Stokes type of amputation present a fitting problem, since the necessary free air space at the end of the socket interferes with the placement of the usual knee mechanism in the artificial leg. Since there is no muscle padding over the bone end, a very accurate fit is necessary in the bottom of the socket.

Stumps in which the muscles have not been fixed over the end of the bone present a problem, since these muscles may retract rather markedly during certain phases of walking and lead to excessively high negative pressure within the socket. The marked stump muscle retraction may be repaired by a surgical revision of the stump, suturing the muscles over the bone by means of stitches through their fascia.[3] The excessive negative pressure may also be reduced by the use of the variable leak rate type of valve.

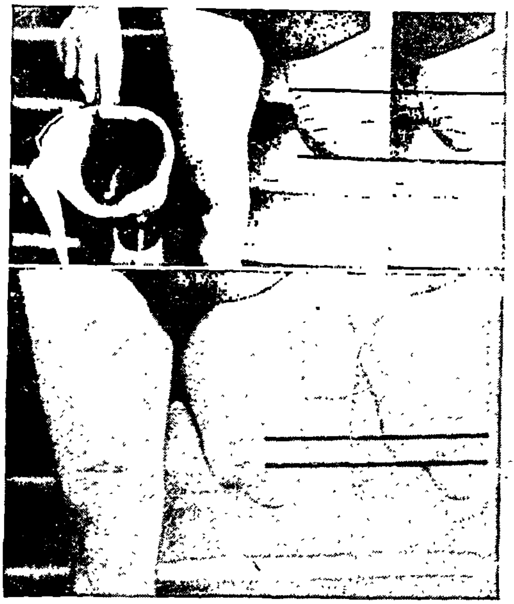

Fig. 2.—Examples of retraction of the stump end when the muscles are tensed (right). The change in shape and size of the stump makes fitting difficult.

AMPUTATION TECHNIQUE

The suction socket can be most easily fitted if the femur is amputated 3 to 4 inches (7.6 to 10 cm.) above the adductor tubercle, and above the supracondylar flare of the femur. In any amputation above this level, all the bone length possible should, of course, be saved. The muscles should not be allowed to retract but should be closed over the bone end without tension by means of sutures placed in the fascia of the muscle. The deep fascia of the thigh and the skin are then closed over the muscles by separate sets of sutures. Inman,[4] reports that this is the standard procedure in preparing a stump for a suction socket in Germany, where the suction socket has been used for a number of years.

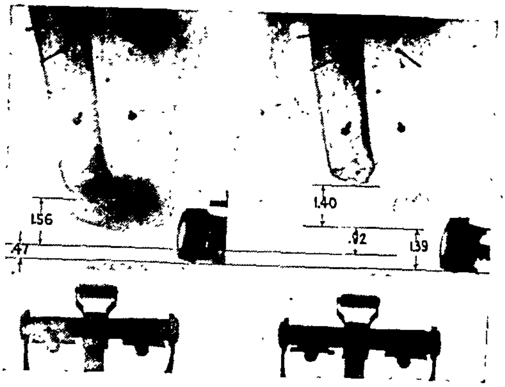

Fig. 3.—Roentgenograms of a stump actually in a suction socket, showing the effect of marked muscle retraction. Weight bearing is shown on the left. On the right, piston action producing a high negative pressure is shown, in a nonweight bearing condition with the muscles tensed.

POSTOPERATIVE CARE

The sutures should be removed at the end of the tenth day after the operation. During these 10 days the patient should lie on his face in bed at least one hour a day to prevent the beginning of a flexion contracture of the hip. After removal of the sutures, the stump should be wrapped with an elastic bandage. This wrapping must cover the end of the stump by means of reverses, and it must come up to the inguinal fold in front of the leg and the gluteal fold behind, so that the subcutaneous tissues of the leg will be of uniform thickness. If only the lower portion of the stump is wrapped, the fitting of a suction socket will be considerably more difficult. In order to maintain the position of the wrapping high at the top of the stump, it is necessary to put on a spica type of bandage with several turns taken about the waist

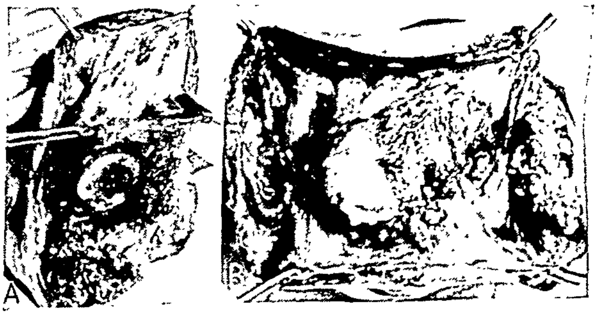

Fig. 4.—*A*, layers for closure of thigh amputation. Upper portion shows skin and fascia lata divided at the same level; center shows quadriceps muscle with its overlying fascia; lower portion shows femur divided above the supracondylar flare. *B*, thigh stump with muscular layer closed. In the top part clamps on the anterior fascia lata are seen; in the bottom part, clamps on the posterior fascia lata. Interrupted sutures through the fascia of muscles close the muscles over the femur. There should be minimal dissection of the fascial planes. In *B* it is difficult to distinguish between the fascia lata and the surface of the muscle, because the surface of the muscle has not been disturbed.

4. Eberhart, H. D.; Inman, V. T.; Rosenkranz, G., and McKennon, J. C.: Summary of European Observations, Summer, 1949; Report to Advisory Committee on Artificial Limbs, National Research Council, Washington, D. C. October 1949.

and the top of the stump in a figure of eight. The purpose of the wrapping with an elastic bandage is to prevent the excessive accumulation of subcutaneous fat. The bandage does not interfere with development of the muscles. The stump should be bandaged day and night. The bandage may be removed during exercising or bathing of the stump.

The muscle exercises are divided into two groups: first, those involving the muscles of the hip which have not been disturbed by the amputation; second, those mobilizing muscles of the thigh that have been divided in the process of amputation. When the sutures are removed, active exercise of the hip muscles should be started. Extension and abduction should be particularly stressed, and the hip should be carried through a full range of active motion in all directions. As soon as the end of the stump is nontender and able to tolerate a cuff, exercises against resistance should be started. It is of great importance in older amputees to prevent the formation of hip flexion contracture. The hip flexors should be stretched daily with the patient lying on his face and the stump placed on a pillow. Exercise of the severed muscles of the thigh should also be started 10 days after the operation. These should consist of alternate contractions of the extensor and flexor muscles of the knee. At first, no attempt should be made at vigorous contractions, because of pain and the possibility of disrupting some of the muscle sutures. At the end of six weeks, vigorous contractions of these severed muscles may be started.

Fitting of the suction socket may be started when the site of amputation is completely healed and painless. Fitting may occasionally be started as early as six weeks following amputation, though 8 to 12 weeks is a more usual time for such fitting.

SUMMARY AND CONCLUSIONS

Unsuccessful attempts at fitting above knee suction socket artificial legs are usually the result of two factors: first, the inability of the amputee to spare the necessary time for fittings; and second, the presence of either a flabby, poorly muscled stump or a very short stump. Difficulty is also occasionally encountered in very long stumps or in stumps with marked retraction of the muscles. On the other hand, even very difficult stumps can be fitted if the amputee is cooperative and persistent in his attempts to obtain the fitting. The amputee can be spared a great deal of lost time and disappointment if these facts are explained to him at the time of prescription of the artificial leg.

The most favorable type of amputation for fitting a suction socket above knee prosthesis is an amputation which is 3 or 4 inches (7.6 or 10 cm.) above the adductor tubercle, and in which the muscles have been approximated over the bone end by means of sutures in the fascia of the muscle.

The most important factors in postoperative care are (1) the prevention of hip flexion contracture, (2) the wrapping of the stump with an elastic bandage and (3) the initiation of active exercise to the hip muscles. The stump-wrapping bandage should completely cover the stump and be high in the inguinal and gluteal fold. To accomplish this, a spica type of bandage around the hip is necessary. Active exercises to the hip muscles beginning 10 days after the operation, together with exercises of the muscles which have been severed, will make the fitting of the suction socket and the gait training of the patient much simpler. The fitting of the artificial leg may be begun between six and 12 weeks after the amputation, as soon as the stump is well healed and painless.

1674 Franklin Street.

ABSTRACT OF DISCUSSION

Dr. Robert Mazet, Jr., Los Angeles: Dr. Bechtol's presentation is a masterpiece in its brevity. Our ideas have undergone some changes. It was first thought that the top of the socket should be quite rectangular in shape, with a wide and high ischial seat, rather pronounced cutouts for the gluteal and adductor muscles, and extension on the lateral side to just below the top of the great trochanter. A fairly tight uniform fit throughout was considered essential. We have learned that the extreme height laterally is not necessary. This has, therefore, been discontinued. Early in the program, excessive ischial irritation on weight bearing, pressure just distal to the ischium when sitting and loss of suction on sitting were common complaints. Prolongation of the ischial seat laterally, permitting some weight bearing in the gluteal area, and decreasing its height and depth have proven helpful. Its sharp inner border has been rounded off. A shallower gluteal cutout is now used. These modifications have resulted in a loss of some of the rectangular shape. The undercut anteriorly is less pronounced than formerly. The snug fit throughout is not desirable. Edema was often caused, not by a tight fit at the top, but by a tight fit at the distal end. This was particularly noticeable in stumps with partial end-bearing. The explanation for this is not entirely clear. Our buckets are now made with a tight-fitting top, close contact anteriorly and a loose fit between stump and bucket elsewhere. They are somewhat barrel-shaped. Dr. Bechtol mentioned changes in the stump contour. In few cases has the anticipated initial shrinkage in stump circumference occurred. Many stumps have increased in size as the musculature of the thigh developed. Sometimes a relative change has occurred in stumps with a large adductor roll. The roll has been pulled down into the bucket and disappeared. The subcutaneous fat of the roll appears to be compressed and absorbed. At the same time, there is an increase in the subcutaneous fat of the distal portion of the stump. Sebaceous cysts may be prevented by pulling the adductor roll well down into the bucket.

Dr. Paul E. McMaster, Los Angeles: In general, our observations in the Los Angeles area coincide with those of Dr. Bechtol. We have had 90 patients who were veterans. Seventeen have been rejected, and 66 have been successfully fitted with suction sockets and are using this prosthesis regularly, most of them for a period of over a year. Seven patients have been fitted, who, for various reasons, have had to change or convert to the conventional type of prosthesis. Our failures have been due to two main causes: uncooperative patients, who can best be described as persons mentally insufficient and unable or unwilling to cooperate, and the inability of some patients, because of occupation or distance, to make and/or keep appointments for the multiple refittings that are necessary for successful results with the suction socket. All our patients whose psychogenic status might be questionable are referred for psychiatric evaluation. This was routine during the earlier stages of our program, and a few patients have been turned down because of unfavorable reports. Bony stumps at least 4½ to 5 inches (10 to 12.7 cm.) from the pubic tubercle are considered the minimal length for satisfactory fitting. We measure from the pubic tubercle, rather than from tip of trochanter, because it is easier, as a rule, to locate accurately. This is the measurement most commonly used by our limb fitters, and it is constant, requiring only that the stump be in normal alignment, neither adducted nor abducted. The optimum amputation site is at about the junction of the middle and lower thirds of the thigh. Knee length or slightly shorter stumps present definite fitting problems and are not desirable. Dr. Bechtol mentioned the need for suturing the muscles over the stump end. It is doubtful, in my mind, if this is necessary. It is estimated that only a very few, if any, of our patients had had this done, and we have had to make no stump revisions to correct excessive retraction of muscles. It was also stated that excessive negative pressure could be reduced by the use of the variable leak rate type of valve. We believe high negative pressure is an indication of improper fitting of the socket, and the improper fitting should be corrected, rather than an attempt made to correct the pressure by valve changes. Also, we believe that the ordinary exhaust type valve, rather than the breathing or two way valve, is, in general, superior. Wrapping the stump with an elastic bandage postoperatively, and carefully carrying this to the inguinal and gluteal regions with a spica type wrapping is important. This, as Dr. Bechtol pointed out, will tend to decrease excessive subcutaneous fat. Many of our older amputees, after having worn a conventional leg, develop large adductor rolls of fat. With careful fitting of a socket and the repeated pulling down of these rolls into the socket with the stump sock, they can in time be made to disappear. Dermatitis of fairly marked degree has occurred in a few of our patients. The apparent causes were excessive perspiration and poor daily hygiene of stump. The former may be helped with silicagel in the socket; also, a breather type valve will help in some cases. The use of a 0.5 to 1 per cent solution of formaldehyde wiped off with alcohol may help. Daily washing with ordinary soap and warm water usually is sufficient to keep stumps in excellent condition. I would like to ask Dr. Bechtol what his experience has been with fitting a suction socket to the arteriosclerotic amputee of the 60 to 70 year group.

Dr. Charles O. Bechtol, Oakland, Calif.: Age in itself is no contraindication to the use of the suction socket. Most of our older patients, however, have poor coordination and flabby stumps and may have circulatory difficulty in the remaining leg. These in themselves, may be contraindications to the use of the suction socket. With regard to suturing the muscle over the end of the bone, we have had at least two dozen cases in which the muscles have not been sutured. In all of them, the fitting of the suction socket has been considerably more difficult. The shape of the suction socket is exceedingly variable; there is no rule of any type by which you can lay down standard patterns for the shape. Edema has almost always been due to a tight fit and, strangely enough, a tight fit in the lower portion of the socket. The patient can tolerate fairly tight fit at the top of the socket, but fit must be loose in the lower two-thirds. The variable leak rate valve mentioned is only applicable to about 10 per cent of the suction socket wearers; it is usually applied in those cases in which very marked stump muscle retraction occurs. It should be reemphasized that most amputees feel that the suction socket presents advantages which outweigh any difficulties or delays encountered in fitting.

REPAIR OF SURFACE DEFECTS OF THE FOOT

RESURFACING THE FOOT BY PLASTIC SURGERY FOR DEFECTS SUCH AS PLANTAR WARTS AND TRAUMATIC, THERMAL AND RADIATION LESIONS

James Barrett Brown, M.D.
and
Minot P. Fryer, M.D., St. Louis

Defects and losses of the skin and subcutaneous tissues of the foot cause major discomfort and disability, and trouble continues until there is complete permanent healing. Resurfacing the foot with free grafts and flaps may result in adequate results for function and comfort, but the processes may be technically difficult, and also troublesome for the patient. Therefore, it is important to realize that there are numerous qualifications and limitations of this resurfacing in trying to secure solid permanent closure of even a small defect. Problems encountered, including those found in military surgery, have been recorded,[1] and some of the present material is based on these references.

ANATOMY OF THE FOOT

In its skin and subcutaneous makeup the sole is a special congenital organ or structure, and is not developed individually. The same sort of tissue does not occur elsewhere in the body (except in the palm), and if it is once lost it can be only substituted for. Tissues transplanted to the sole from other areas do not undergo metaplasia to become a normal sole, nor will walking on the new tissue cause it to do so, and the substituted area will require care and protection to prevent irritation and ulceration. Because of this, transfer of skin from the opposite sole might seem indicated, but the transfer would result in added debilitation in most instances. If hair-bearing skin is transplanted to the sole, the hair will continue to grow, except as it is worn off. This is because the foreign skin does not take on the characteristic of producing the thick keratinized layer that occurs in the normal sole.

The surface over the normal heel cord is also specialized, and, though the skin over the rest of the dorsum is not as specialized, the whole foot including the malleoli and the dorsum requires an intact surface for the protection of these areas. In surgical procedures on the foot, care is taken to keep incisions at a minimum and an attempt made to assure adequate coverage and prompt healing. That deep healing and proper function are dependent on an intact surface is nowhere truer than in the foot.

The sensory nerve supply of the foot is of great importance, and if anesthesia occurs either in scarred or repaired areas, there is apt to be trouble from trauma and ulceration. If nerves remain present in the general area, sensation will develop in both grafts and flaps to a worthwhile protective degree, and the grafts may develop practically normal sensation. But if the nerve supply has been so interrupted that there are no nerves available, there is apt to be chronic ulceration to start with, and it may continue in the repaired area. The care of the anesthetic foot is tedious but must be vigilant if trouble is to be avoided.

DIFFERENT METHODS OF REPAIR

Direct suture of the skin of the foot after a loss, especially in the sole, is limited to repair of linear defects, but is not effective over bearing surfaces. In the center of the sole, for example, some excellent results can be obtained; however, deep sutures of any kind are apt to cause trouble, and deep wire is not used because of possible irritation and wart formation. Simple direct suturing and careful strapping and bandaging are essential parts of the operation.

Leaving small wounds open to heal in themselves in the sole may be successful in "silent" areas such as the middle of the arch, but in bearing areas the resultant scar may be so painful that a secondary repair is necessary.

Local or adjacent flaps are used when possible, but as there is little extra skin in the foot, closing a round defect of any size in the sole can be similar to trying to close a knot hole in a board. Care also must be taken in mobilizing any flaps to avoid interrupting an important nerve or blood supply.

Rotated flaps or laterally shifted flaps are good for use in the covering of bearing points and for repairing defects consisting of warts or small scars; but, here again, nerve and blood supply should be considered carefully.

Filleted toe flaps are occasionally utilized, but such amputation procedures should be avoided whenever possible.

Permanent pedicle blood-carrying flaps to increase vascularity in avascular areas are of great service in radiation lesions or in the covering of areas after resecting dense deep scars. These may be rotated flaps in the sole, or over the dorsum or dorsum to sole flaps. This suggestion in the general concept of flaps is the subject of another report to be published.

Free thick split skin grafts are used generally, if there is an adequate subcutaneous pad of tissue to carry the graft and form a supporting cushion. If this pad is present, the repair is better with a free graft surface than any flap transferred from a distance. By this plan much time can be saved and morbidity reduced. Free grafts may be used as a temporary or trial measure in burns, radiation lesions, avulsions and cancer, and a flap put in secondarily if it becomes necessary. The occasional extra operation is well worth while in the consideration of trying to avoid a cumbersome cross leg flap.

This "skin graft dressing" method may save many extremities, and amputation can be left to secondary consideration if nerve and blood vessel supply to even a badly denuded extremity is intact. One of the most dramatic cases of this kind was that of a boy from one of whose feet the entire skin and the anterior third were torn off in a railroad accident. He was brought in for midleg amputation, but instead, the entire remaining part of the foot and the ankle were "dressed" in thick split grafts. The patient's foot was saved by means of this one single operative procedure. His care of the grafted foot was not excessive, even for a growing boy, and, aside from packing his shoe where his toes were missing, he had little difficulty and participated in normal athletics.

Thick split grafts are usually taken from high on the back of the thigh and buttocks with a simple graft knife and suction retractor. Pressure fixation dressings of fine mesh with bismuth tribromophenate (xeroform®), or petrolatum (vaseline®) gauze and surgical waste are carefully applied, fixing ankle and knee joints with adequate padding, gauze rolls and adhesive.

Full thickness grafts may be used if desired, especially for small defects when a suitable one can be obtained from the inguinal region.

Cross leg flaps are considered as a method for repair when other methods will not suffice. These flaps, the same as grafts, do not give a normal sole, because the skin of the flap does not undergo metaplasia into a heavy keratotic sole. Other difficulties in their use are cumbersomeness of procedure and damage to the donor site, necessitating its repair, and use of these flaps may be inadvisable because of the age of the patient, or joint fixation or some other disability.

Repairing donor sites of flaps may give difficulty if the sites are not advantageously selected, and as much disability has been observed resulting from the donor site as from the original trouble.

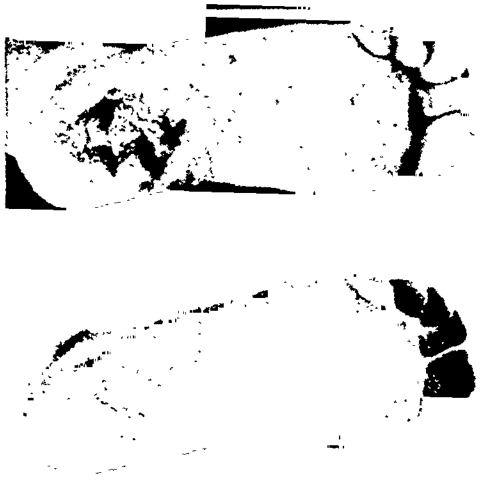

Fig. 1.—Top, foot after prolonged treatment, including radiation and tedious preparation of abdominal tubed flap (elsewhere), for wart of heel. Bottom, foot after repair with free split graft and permanent pedicle flap from side of foot with graft for donor site of pedicle in one operation. Distant flap was removed without necessity of use.

Delayed flat flaps, considered the safest to transfer, depend on gradual cutting off of the blood supply, taking at least two operations. To completely outline and undermine a flap and raise it on its pedicle and then put it back in its bed does not delay the blood supply of the flap, but simply delays the transfer to a later stage. The usual procedure is to open the long axis in two parallel lines, undermine between, and close the incisions. The distal end is cut across secondarily in three to 10 days and closed, usually under local anesthesia.

The delayed flap is transferred when there is no swelling, induration or redness, and no suggestion of inadequate circulation through the pedicle.

A variation of the above is the implantation of a split graft under the flap at the time it is first elevated in order to have the donor site this much closed when the flap is used, but this method is not often resorted to on this service.

Tubed flaps are started in about the same manner as delayed flat flaps, except that the cut edges are closed sive retraction of muscles. It was also stated that excessive negative pressure could be reduced by the use of the variable leak rate type of valve. We believe high negative pressure is an indication of improper fitting of the socket, and the improper fitting should be corrected, rather than an attempt made to correct the pressure by valve changes. Also, we believe that the ordinary exhaust type valve, rather than the breathing or two way valve, is, in general, superior. Wrapping the stump with an elastic bandage postoperatively, and carefully carrying this to the inguinal and gluteal regions with a spica type wrapping is important. This, as Dr. Bechtol pointed out, will tend to decrease excessive subcutaneous fat. Many of our older amputees, after having worn a conventional leg, develop large adductor rolls of fat. With careful fitting of a socket and the repeated pulling down of these rolls into the socket with the stump sock, they can in time be made to disappear. Dermatitis of fairly marked degree has occurred in a few of our patients. The apparent causes were excessive perspiration and poor daily hygiene of stump. The former may be helped with silicagel in the socket; also, a breather type valve will help in some cases. The use of a 0.5 to 1 per cent solution of formaldehyde wiped off with alcohol may help. Daily washing with ordinary soap and warm water usually is sufficient to keep stumps in excellent condition. I would like to ask Dr. Bechtol what his experience has been with fitting a suction socket to the arteriosclerotic amputee of the 60 to 70 year group.

DR. CHARLES O. BECHTOL, Oakland, Calif.: Age in itself is no contraindication to the use of the suction socket. Most of our older patients, however, have poor coordination and flabby stumps and may have circulatory difficulty in the remaining leg. These in themselves, may be contraindications to the use of the suction socket. With regard to suturing the muscle over the end of the bone, we have had at least two dozen cases in which the muscles have not been sutured. In all of them, the fitting of the suction socket has been considerably more difficult. The shape of the suction socket is exceedingly variable; there is no rule of any type by which you can lay down standard patterns for the shape. Edema has almost always been due to a tight fit and, strangely enough, a tight fit in the lower portion of the socket. The patient can tolerate fairly tight fit at the top of the socket, but fit must be loose in the lower two-thirds. The variable leak rate valve mentioned is only applicable to about 10 per cent of the suction socket wearers; it is usually applied in those cases in which very marked stump muscle retraction occurs. It should be reemphasized that most amputees feel that the suction socket presents advantages which outweigh any difficulties or delays encountered in fitting.

REPAIR OF SURFACE DEFECTS OF THE FOOT

RESURFACING THE FOOT BY PLASTIC SURGERY FOR DEFECTS SUCH AS PLANTAR WARTS AND TRAUMATIC, THERMAL AND RADIATION LESIONS

James Barrett Brown, M.D.
and
Minot P. Fryer, M.D., St. Louis

Defects and losses of the skin and subcutaneous tissues of the foot cause major discomfort and disability, and trouble continues until there is complete permanent healing. Resurfacing the foot with free grafts and flaps may result in adequate results for function and comfort, but the processes may be technically difficult, and also troublesome for the patient. Therefore, it is important to realize that there are numerous qualifications and limitations of this resurfacing in trying to secure solid permanent closure of even a small defect. Problems encountered, including those found in military surgery, have been recorded,[1] and some of the present material is based on these references.

ANATOMY OF THE FOOT

In its skin and subcutaneous makeup the sole is a special congenital organ or structure, and is not developed individually. The same sort of tissue does not occur elsewhere in the body (except in the palm), and if it is once lost it can be only substituted for. Tissues transplanted to the sole from other areas do not undergo metaplasia to become a normal sole, nor will walking on the new tissue cause it to do so, and the substituted area will require care and protection to prevent irritation and ulceration. Because of this, transfer of skin from the opposite sole might seem indicated, but the transfer would result in added debilitation in most instances. If hair-bearing skin is transplanted to the sole, the hair will continue to grow, except as it is worn off. This is because the foreign skin does not take on the characteristic of producing the thick keratinized layer that occurs in the normal sole.

The surface over the normal heel cord is also specialized, and, though the skin over the rest of the dorsum is not as specialized, the whole foot including the malleoli and the dorsum requires an intact surface for the protection of these areas. In surgical procedures on the foot, care is taken to keep incisions at a minimum and an attempt made to assure adequate coverage and prompt healing. That deep healing and proper function are dependent on an intact surface is nowhere truer than in the foot.

The sensory nerve supply of the foot is of great importance, and if anesthesia occurs either in scarred or repaired areas, there is apt to be trouble from trauma and ulceration. If nerves remain present in the general area, sensation will develop in both grafts and flaps to a worthwhile protective degree, and the grafts may develop practically normal sensation. But if the nerve supply has been so interrupted that there are no nerves available, there is apt to be chronic ulceration to start with, and it may continue in the repaired area. The care of the anesthetic foot is tedious but must be vigilant if trouble is to be avoided.

DIFFERENT METHODS OF REPAIR

Direct suture of the skin of the foot after a loss, especially in the sole, is limited to repair of linear defects, but is not effective over bearing surfaces. In the center of the sole, for example, some excellent results can be obtained; however, deep sutures of any kind are apt to cause trouble, and deep wire is not used because of possible irritation and wart formation. Simple direct suturing and careful strapping and bandaging are essential parts of the operation.

Leaving small wounds open to heal in themselves in the sole may be successful in "silent" areas such as the middle of the arch, but in bearing areas the resultant scar may be so painful that a secondary repair is necessary.

Local or adjacent flaps are used when possible, but as there is little extra skin in the foot, closing a round defect of any size in the sole can be similar to trying to close a knot hole in a board. Care also must be taken in mobilizing any flaps to avoid interrupting an important nerve or blood supply.

Rotated flaps or laterally shifted flaps are good for use in the covering of bearing points and for repairing defects consisting of warts or small scars; but, here again, nerve and blood supply should be considered carefully.

Filleted toe flaps are occasionally utilized, but such amputation procedures should be avoided whenever possible.

Permanent pedicle blood-carrying flaps to increase vascularity in avascular areas are of great service in radiation lesions or in the covering of areas after resecting dense deep scars. These may be rotated flaps in the sole, or over the dorsum or dorsum to sole flaps. This suggestion in the general concept of flaps is the subject of another report to be published.

Free thick split skin grafts are used generally, if there is an adequate subcutaneous pad of tissue to carry the graft and form a supporting cushion. If this pad is present, the repair is better with a free graft surface than any flap transferred from a distance. By this plan much time can be saved and morbidity reduced. Free grafts may be used as a temporary or trial measure in burns, radiation lesions, avulsions and cancer, and a flap put in secondarily if it becomes necessary. The occasional extra operation is well worth while in the consideration of trying to avoid a cumbersome cross leg flap.

This "skin graft dressing" method may save many extremities, and amputation can be left to secondary consideration if nerve and blood vessel supply to even a badly denuded extremity is intact. One of the most dramatic cases of this kind was that of a boy from one of whose feet the entire skin and the anterior third were torn off in a railroad accident. He was brought in for midleg amputation, but instead, the entire remaining part of the foot and the ankle were "dressed" in thick split grafts. The patient's foot was saved by means of this one single operative procedure. His care of the grafted foot was not excessive, even for a growing boy, and, aside from packing his shoe where his toes were missing, he had little difficulty and participated in normal athletics.

Thick split grafts are usually taken from high on the back of the thigh and buttocks with a simple graft knife and suction retractor. Pressure fixation dressings of fine mesh with bismuth tribromophenate (xeroform®), or petrolatum (vaseline®) gauze and surgical waste are carefully applied, fixing ankle and knee joints with adequate padding, gauze rolls and adhesive.

Full thickness grafts may be used if desired, especially for small defects when a suitable one can be obtained from the inguinal region.

Cross leg flaps are considered as a method for repair when other methods will not suffice. These flaps, the same as grafts, do not give a normal sole, because the skin of the flap does not undergo metaplasia into a heavy keratotic sole. Other difficulties in their use are cumbersomeness of procedure and damage to the donor site, necessitating its repair, and use of these flaps may be inadvisable because of the age of the patient, or joint fixation or some other disability.

Repairing donor sites of flaps may give difficulty if the sites are not advantageously selected, and as much disability has been observed resulting from the donor site as from the original trouble.

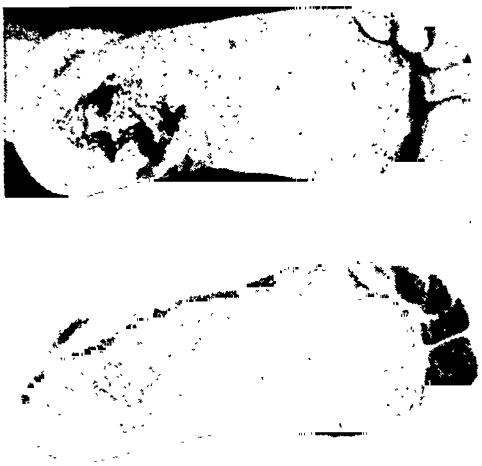

Fig. 1.—Top, foot after prolonged treatment, including radiation and tedious preparation of abdominal tubed flap (elsewhere), for wart of heel. Bottom, foot after repair with free split graft and permanent pedicle flap from side of foot with graft for donor site of pedicle in one operation. Distant flap was removed without necessity of use.

Delayed flat flaps, considered the safest to transfer, depend on gradual cutting off of the blood supply, taking at least two operations. To completely outline and undermine a flap and raise it on its pedicle and then put it back in its bed does not delay the blood supply of the flap, but simply delays the transfer to a later stage. The usual procedure is to open the long axis in two parallel lines, undermine between, and close the incisions. The distal end is cut across secondarily in three to 10 days and closed, usually under local anesthesia.

The delayed flap is transferred when there is no swelling, induration or redness, and no suggestion of inadequate circulation through the pedicle.

A variation of the above is the implantation of a split graft under the flap at the time it is first elevated in order to have the donor site this much closed when the flap is used, but this method is not often resorted to on this service.

Tubed flaps are started in about the same manner as delayed flat flaps, except that the cut edges are closed in a tube formation and the open area underneath is grafted or closed. If a large flat "pan cake" is to be used on the end of the tube, this is delayed secondarily, as is the end of a flat flap. If only the tube is to be used, it is not usually necessary to delay the distal end; however, this can be an added precaution.

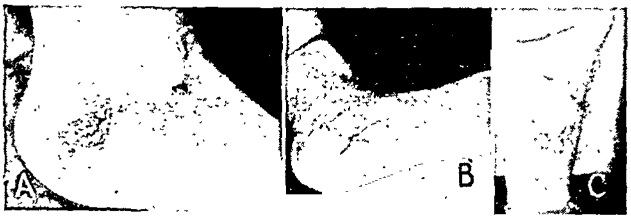

Fig. 2.—*A*, defect of 40 years duration resulting from a railroad accident. *B*, defect, after repair with direct cross leg flap in two operations, one on and one off, and two adjustments of the edges. *C*, donor site from which the flap was taken.

There are several methods of determining evidence of adequate circulation in a tubed flap, the best one of which, as learned by experience, is the finding of no redness, swelling or other sign of failing circulation. Chemical methods depending on injections and determination of absorption of test materials may give information about the tube, proximal to a tourniquet on one end, but will not help for the flat end or "pan cake" if one is used with the flap.

The procedure for combined flat and tubed pedicle flaps is about the same as that described for utilizing a flat area on the end of a tube. The tube in these instances is for ease of transfer, especially if the pedicle has to be twisted.

Cross sole flaps are mentioned only in order to repeat that in a large series they might result more in added disability than in benefit.

Direct cross leg flaps are most useful and simple and are relied on when the requirements of the defect are such that a donor site can be arranged satisfactorily. A short, broad pedicle is used, rather than a long, flat or tubed pedicle; the process is much quicker and easier and more economical, and the repair is possibly somewhat better because the flap is made to order to fit the defect during the first operation rather than by separate procedures. These flaps require that the foot can be carried to the donor site, in the same way that the hand can be carried to the abdomen so that delayed tubed or double pedicle flaps are scarcely ever needed for the hand and forearm. The short broad direct pedicle flap is turned back, and the foot is brought into place and anchored, either with or without dressing the donor site in free grafts.

Sites of flaps for certain defects can be more or less standardized, but each defect is an individual problem. The best site is the one the patient finds the most comfortable through practice, taking into consideration the avoidance of knee joint, nerves, and vessels.

Pocket flaps are ones made by simply opening an area on the leg, through a single long incision, usually made transversely below the knee, and undermining a pocket. These are for the end of the foot when it can be implanted into the pocket through the single opening. The procedure was developed at Valley Forge Hospital and used there extensively in military services with great saving in time. These flaps were often called "slash" flaps, but "pocket" seems more appropriate.

Double heel and toe flaps are utilized along the side of the knee for replacing the front and back of the foot in a single direct flap procedure. A pocket flap can be used for the toe and a direct flap for the knee. These flaps may seem bizarre for civil needs but are not bizarre in military plastic surgery, where resurfacing of the foot is a constant problem.

Jump flaps from the abdomen, with the forearm as a carrier, utilize the broad short direct pedicle method[2] of flap transfer. A large direct flap from the abdomen is put on the forearm and transferred secondarily to the foot.

There are variations of preparation of these flaps, including folding them on themselves to allow an interval between taking up and use on the foot, but the essential principles are the same when the short broad direct pedicle is used for rapid transfer of tissue.

It is necessary to use the thigh for larger flaps or for large flat or tubed flaps, and attention is again called to possible trouble from donor sites on the opposite lower leg. Small flaps, however, can usually be obtained successfully from the opposite lower leg without serious trouble in the donor site.

Dorsum-to-sole flaps are utilized as delayed flaps and, though limited in size and extent of transfer, are very useful around the edges of the sole over bearing points. These flaps may be direct, lateral shifts or delayed pedicles rotated down in place and may be permanent blood-carrying.

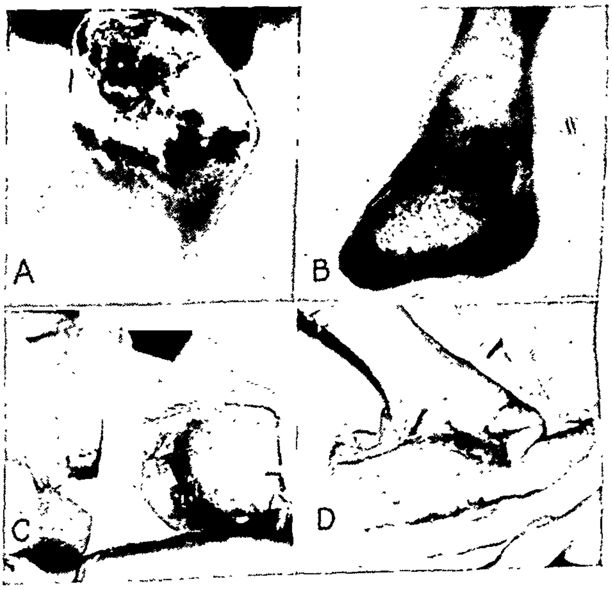

Fig. 3.—*A* and *B*, freezing injury with loss of all toes, and open end of foot, which was repaired with direct cross leg pocket (or slash) flap, in two operations, one on and one off. *C*, illustration of method of fixation of this pocket flap. *D*, illustration of method of using two direct flaps in a single operation for covering freezing injury, loss of toes and heel.

Closed wound flaps are formed by doing a split graft "dressing" of all raw areas. This may be advantageous, but it is not necessary either on the foot or elsewhere in

---

2. Footnote 1c. Brown, J. B., and others: Direct Flap Repair of the Arm and Hand: Preparation of Gunshot Wounds for Repair of Nerves, Bones and Tendons, Ann. Surg. 122: 706-715 (Oct.) 1945.

the body if adequate dressing care can be given the operative field. Serious infection and fibrosis do not take place around a defect just because the donor site and pedicle of a flap have not been grafted.

The simplest, most direct methods are usually best for fixation of a foot to a cross leg flap, or an arm to a foot. This starts with the most comfortable position, as determined by practice, and with the simplest equipment. Adhesive, padding, and pillows with foam rubber over pressure points usually suffice and are the most comfortable. But plaster of paris with suitable struts and angle supports of light splint boards incorporated in the plaster may be needed to hold the knee up from the bed, or elsewhere to prevent unnecessary gravity, rotation and twisting. Padding should be copious with foam rubber, and suitable openings should be planned for inspection of the flap.

Detaching the flaps can be done in 14 to 21 days under local anesthesia, in stages if necessary; or, if there is a heel or two sides of the foot to cover, a secondary flap delay may be indicated before detachment is done.

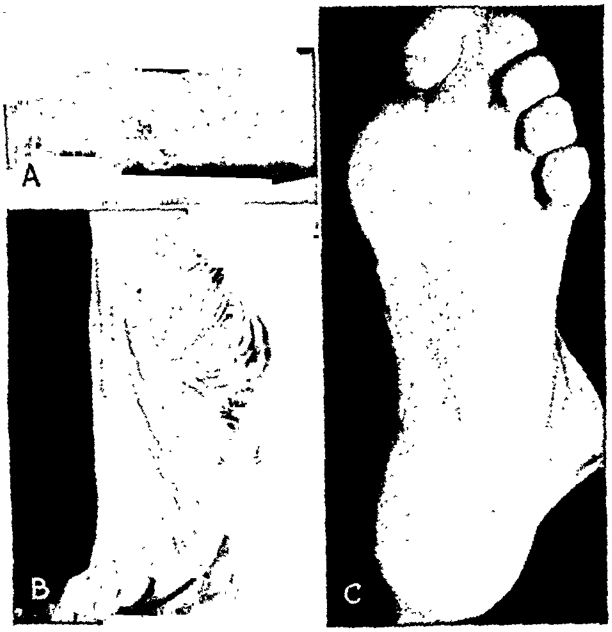

Fig. 4.—*A*, crippling wart with radiation lesion which was resected and repaired with a thick split graft in one operation. *B*, *deformed position of* foot, which had been assumed *to find relief from* excessive pain, with callus over instep from shoe pressure. *C*, foot after surgical repair.

Repairs of donor sites are done with free split grafts, usually at a time slightly later than that of the detachment, since there are some noteworthy contractures and by waiting the grafted area may be smoother. For those flaps that have been "dressed" in grafts to start with, there is usually some further closure or grafting to do when the flap is detached.

Final adjustment of flap is usually done several days after detachment but can be done at the time of detachment if conditions are favorable.

A suitable bed is as necessary for a flap as for a graft since a flap may not attach itself over avascular areas, or will it over dead bone tendon or fascia. It may pick up circulation around the edges, only to have a chronic sinus persist as long as there is deeper trouble.

Once the plantar fascia is exposed and infected or necrotic it is usually a source of prolonged trouble, and resurfacing is contraindicated until all dead material is cut off or removed. The same is true of the tendons, and these two elements may cause prolonged morbidity in open wounds or, if they occur, under flaps. Free grafts, of course, will not grow over such areas.

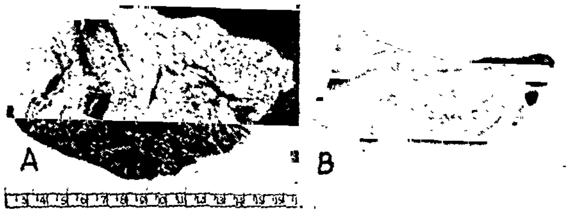

Fig. 5.—*A*, extensive wart and radiation lesion, closely approaching carcinoma. *B*, lesion after resection and repair with free split skin graft in one operation. Function is satisfactory for golf and normal activities.

Debridement in injured feet should be careful to eliminate dirt and dead tissue, but widespread cutting away of tissue should be done only after careful consideration, since there is so little extra or collapsible tissue in the foot.

Failing circulation in the extremities leads to questionable repairs of defects, and opens the possibility of repeat ucleration in the grafted site, so that the ultimate success of a repair in a circulatory dyscrasia or secondary impairment is uncertain, as it may be in leg ulcers. All of the processes involved in leg ulcers are not understood, but a basic point is that in some instances the circulation of the leg does not seem to have caught up with the requirements of the upright position.

Decubitus ulcers in persons with normal nerve supply usually respond to free grafting. Those in paraplegics may respond to the "take" of a graft but are subject to the same recurrent break down as any other area of anesthesia.

Plantar warts are the reason for most repairs of the sole. It is difficult for most patients and institutions and some medical echelons to understand how an insignificant thing like a wart can necessitate so much trouble and surgical work. An answer can be that the wart doesn't amount to anything, but its location does; and, to repeat, once the sole is open, disability exists until the sole is healed, free of trouble, and especially free of the wart. A painful wart might be likened to a cinder in the eye or a tack in a shoe, not much in *themselves, but* exceedingly painful and disabling.

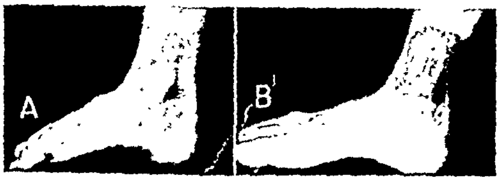

Fig. 6.—*A*, atomic radiation lesion in a laboratory worker. *B*, lesion after it was resected and repaired in one operation with a thick split graft.

Added to the wart itself may be a radiation lesion, and, to this, a malignant change, so that the problem is two fold: one, to get rid of the lesion, and, two, to give a satisfactory repair.

For repair of warts, scars and radiation lesions in the center of the foot, simple linear excision and closure may suffice; if not, a free thick split graft is used if sufficient pad is left to support it. Flaps from the side, or rotated, or from the dorsum may be needed, but the bearing surfaces over the first and fifth metatarsal heads and over the heel are not shifted to repair any defect. To do so would leave a scar over a bearing surface that might require a secondary repair even if a free graft were used to close the area.

Lesions over these three important bearing surfaces are not excised and closed by direct suture, because this would leave a disabling scar. Instead, there is usually a lateral shift from the midline, or a rotation flap closure from behind the toe, with repair of the donor site with a free graft.

Replacement of whole sole or large sections of it can be done with free thick split grafts if there is adequate padding left behind. If there is a question as to the adequacy of the padding, the graft can be used as a "dressing" and replaced later with a flap if necessary. Exposure of tendon, nerves, vessels, and, of course, of bone necessitates a thick pedicle flap, either cross leg or jump from the abdomen.

Gun shot wounds and others that avulse the pad usually require some variety of flap repair. Some of the wounds are of small surface area, but leave deep dense scars to the bone that need thick flap repairs in even these very small areas.

Radiation lesions are given special note because they are so prevalent and seem to be frequently missed in diagnosis. They are progressive lesions and are treated by removal, and grafting or flap repair.

Atomic radiation lesions will require the same principals of removal and repair. The fact that tissue which has been subject to radiation does not stand trauma and has poor ability to heal normally may make one hesitate to attempt surgical repairs in such areas, but in this discussion of resurfacing the foot it can be stated that the same principles apply to radiation lesions as to other lesions, with the qualification that there may be difficulty in healing the surgical repairs and there may be secondary deep necrosis, with amputation to be considered.[3]

Thermal injuries, including burns, freezing and immersion foot, are repaired according to the depth of loss with free grafts or flaps as outlined for other repairs.

SUMMARY AND CONCLUSIONS

Relief from intensely painful lesions and from prolonged debilitation may be acquired by comparatively simple procedures. The essential steps are (1) the removal of the lesion, (2) the repair of the defect with a suitable covering, (3) the obtaining of permanent, complete healing at the site of the repair, and (4) proper care by the patient of the substituted tissue to protect it from trauma.

Results of repairs of lesions of the foot vary according to the original disability but usually allow the patient normal activity.

508 N. Grand Blvd.

ABSTRACT OF DISCUSSION

Dr. J. Warren White, Honolulu, Hawaii: In our training, we have been warned against incisions on the sole or over other pressure-bearing surfaces. But many of us have known that we can get by without serious difficulties if we depart radically from such an axiom. Notorious along this line is the valuable longitudinal heel-splitting operation for osteomyelitis of the os calcis, in which the incision goes around the middle of the back of the heel, exposing the inside of the calcaneus in a fish mouth fashion, giving such wonderful exposure of that bone. Fortunately, now, in the days of the antibiotics, this operation is not as necessary as it was formerly, but it is well to know that it can be done with relative impunity. There is one type of graft that many of us have found most useful which Dr. Brown did not mention. I should appreciate his opinion on the use of the full-thickness graft, located in the classification of skin grafts between the time-consuming pedicle graft and the potentially keloid-producing split graft. Dr. Brown can do a split graft with a skill which a great many of us do not possess; therefore, I have been forced to use the full-thickness graft. In Honolulu we have excellently trained plastic surgeons to whom I can take the major problems, but in South Carolina, where I was for so many years, the problems involving indigents had to be solved locally by the orthopedists. We then used the time-consuming Ghormley technique in the avulsed heels, but, aside from that, we have used the full-thickness graft extensively. Most problems requiring its use, in the rural communities have been associated with burns in which healing has been characterized by cicatrization associated with the usual contractures. Hyperflexion or extension contractures of the toes are very common. Since going to Hawaii, I have done with much success many operations in which the hiatus produced by the opening of the transversely incised, contracted cicatrix, not infrequently extending the whole width of the foot, has been filled in by a full-thickness graft, the toes being held in the extreme overcorrected position during healing. The ankle, in which fixed dorsiflexion has resulted from a contracted scar is another area where a large, freely movable graft can be placed advantageously. Contrary to popular opinion, there is no limitation of size that restricts its use. Although I realize that Dr. Brown discounts the value of split skin grafting instruments, I should like to get his opinion on one recently devised by another Dr. Brown. It is manufactured in Indianapolis. This is the new automatic reciprocating mechanism, the dermatome, which I demonstrated at the Orthopedic Academy meeting two years ago in January. It has been most satisfactory. The trouble-producing vacuum part has been eliminated, and it now can be used as easily as one uses a lawnmower.

Dr. James Barrett Brown, St. Louis: The full-thickness graft is the best skin graft for certain areas, but it is not often necessary on the foot. Several things are important in this relation because the skin is so different in thickness over the various parts of the body. For instance, the foot has the thickest keratohyaline layer and about the thinnest derma; the back has the thickest derma and the thinnest epithelium. Therefore, full-thickness grafts from the back are not apt to grow, because the skin is too thick. If Dr. White's plan of using a full-thickness graft is followed, it will be best not to try to grow a full-thickness graft from the back. I had supposed Dr. White took most of his grafts from the abdomen, but he states that he has repeatedly taken them from the back, without the loss of the graft. There may be some difference between our interpretations of "thickness of skin," because if the heavy, full thickness of the skin on the back is used routinely, the graft is not likely to survive since it is too thick. This caution is added because Dr. White asked for an opinion on it. If one takes a thick split graft of about three-fourths thickness, or even one-half thickness, from high on the buttocks to put on an area similar to that on the foot shown by Dr. White, the operation can be done in about a tenth of the time it takes to do a full-thickness graft, and it may be a little better. We frequently use grafts on dirty areas, and, though we try to get them clean, they are sometimes hurried along. In such areas, we do not think the full-thickness grafts should be used, because there is a chance of loss. Split grafts are less apt to be lost, and, if they are, the loss is less important. Split grafts are rough for a time because, apparently, some of the glands get cut in two and may then secrete backward, leaving sebum collections that need evacuation; at least this is a way of explaining the roughness. The glands are kept empty to avoid infection and loss of surface, and, as these may be difficult to ascertain, it is best to keep close watch for several weeks. Dr. Brown, who developed the electro-dermatome, figured it out in a Japanese prison camp. He died after he came back to this country, and his wife is going on with the business. I am glad Dr. White mentioned the dermatome, as it seems to provide an excellent method of cutting a split graft. If one can use thick split grafts whenever possible, he is apt to have just as good results, if not better, than if full-thickness grafts were used routinely.

SEGMENTAL RESECTION FOR PULMONARY DISEASES

William S. Conklin, M.D.
and
Harry Westerberg, M.D., Portland, Ore.

Pulmonary resections have been performed successfully for many years, but until 1933 the techniques remained crude and the operations extremely hazardous according to present standards. Staged operations, use of tourniquets and clamps and destruction of lung tissue with cautery all resulted in prolonged morbidity and a mortality horrifying to the surgeon of today.

In 1933 Rienhoff[1] first described the technique of individual isolation and closure of the bronchus and blood vessels at the hilus. This technique, now used in practically all pulmonary resections, has done more than anything else to reduce the operative complications and mortality of these procedures. In 1932 Graham and his colleagues[2] collected a series of 212 lobectomies in which the operative mortality was 34 per cent. By 1947 Kay and associates[3] were able to report 258 consecutive cases of lobectomy for bronchiectasis with only one death, and Jones[4] presented a series of 52 pneumonectomies for bronchogenic carcinoma with only two deaths, surgical mortalities of 0.4 per cent and 4 per cent respectively. Advances in anesthesia, improved preoperative and postoperative care, introduction of antibiotics and the increased experience of thoracic surgeons have also helped lower the operative mortality. It is now believed that the over-all operative mortality for lobectomy is less than 5 per cent and that that for pneumonectomy is well below 20 per cent.

Resection for pulmonary disease does not necessarily require that one or more lobes of the lung be removed in their entirety. Certain lesions can be resected locally by enucleation (fig. 4) or by removing a peripheral wedge-shaped portion of the lung (partial lobectomy). But the indications for such surgery are rare, since the lesions must be peripheral and localized. Such procedures are not suitable for most lesions requiring resection, even though much of the lobe is not involved, since the disease is likely to extend centrally toward the hilus.

Segmental resection, the most recent technical advance in pulmonary resection, resulted from the desire to conserve as much normal lung tissue as possible in cases of bronchiectasis with multilobar involvement. Specifically, the problem was what to do about bronchiectasis in the lingula of the upper lobe of the left lung, so commonly present when there is bronchiectasis in the lower lobe of the left lung. The alternatives formerly available were to resect only the lower lobe, in which case the patient still had bronchiectasis; to remove the entire lung, in which case a great deal of valuable, uninvolved lung would be sacrificed, or to remove the lower lobe and amputate the lingula distal to a clamp applied near the hilus. The latter was usually unsatisfactory due to failure to eradicate the pathological condition and because of the frequency of postoperative complications. The problem was solved by Churchill and Belsey,[5] who appreciated the segmental nature of pulmonary anatomy and demonstrated that the lingula could be dissected completely from the remainder of the upper lobe by dividing the lingular branches of the bronchus and pulmonary artery at their origin. Using the same technique, they also resected the basal segments of the lower lobe leaving the superior division.

It has long been evident that it is not entirely accurate to describe the right lung as having three separate lobes, the left lung two. The fissures which divide these conventionally described lobes one from the other are often incomplete, rudimentary or entirely absent. Particularly is this true of the transverse fissure between the upper and middle lobes of the right lung. Likewise, it is not uncommon to find a rudimentary or even a complete fissure separating one of the conventional lobes into divisions. Such fissures are found most often between the lingula and the remainder of the upper lobe of the left lung and between the superior portion of either lower lobe and its base. Nelson[6] described each lung as possessing four basic parts or "lobes": upper, middle, dorsal and lower. Further study of the anatomic subdivisions of the lung, based on the work of Goldman,[7] Foster-Carter,[8] Brock,[9] Jackson and Huber,[10] Boyden[11] and

others, has resulted in the recognition of 18 bronchopulmonary segments, 10 on the right and eight on the left. The nomenclature proposed by Jackson and Huber (see drawing, page 700, in Kent[12]) has received official recognition by the American Association for Thoracic Surgery and is now widely accepted.

Each bronchopulmonary segment has its own bronchial and vascular components. The segments are separated by a relatively avascular plane, as are "fused" lobes between which the interlobar fissure is incomplete or absent. Intersegmental veins are the only important structures generally found in this plane, and their importance will be referred to later. Subsegments, located more peripherally, with similar bronchovascular components and planes of separation, are also recognized, though their anatomic arrangements are more variable.

The importance of conserving as much functioning lung tissue as possible when performing resections must be emphasized. It is particularly essential when respiratory reserve is limited by disease or previous surgery, or when bilateral resection is contemplated. Nonresected portions of a lung also have tremendous space filling value even when they contribute little to respiratory function. They permit the early filling and obliteration of the pleural cavity, which reduces the incidence of postoperative empyema or reduces the extent of an empyema should one occur. Furthermore, the smaller the volume of lung removed the less overdistention and resultant loss of function that will follow in the portions of the same and the contralateral lungs that are conserved.

Since the original report of Churchill and Belsey in 1939 several authors, notably Clagett and Deterling,[13] Kent and Blades,[14] Blades,[15] Overholt and associates,[16] Ramsay,[17] and Chamberlain and Ryan,[18] have offered modifications and improvements in the technique of segmental resection. They have shown that the techniques of segmental resection are applicable to all bronchopulmonary segments, singly or in groups, and to subsegments; and also that indications for segmental resection exist in diseases other than bronchiectasis.

INDICATIONS

Segmental pulmonary resection has been used most widely in cases of bronchiectasis. Since complications after segmental resection have tended to be more frequent than those after resection of an entire lobe with well developed fissures, it cannot be stated categorically that segmental resection is the procedure of choice in every instance in which it may appear applicable. When most of a lobe is involved in a disease process such as bronchiectasis it may be preferable to resect the entire lobe rather than to assume the added risk of trying to save an uninvolved segment that will contribute little to space filling and to function.

Application of segmental resection to bronchiectasis is dependent on preoperative bronchographic studies, filling all possible segments with iodized oil, and it is based on the assumption that adequate bronchography will determine the entire extent of the disease process. Studies reported by Moore and his colleagues[19] indicate that advanced pathological changes may be present in segments that show no evidence of bronchiectasis roentgenographically when they adjoin segments that do. Whether the less advanced changes may yet be reversible or are likely to be progressive has not been established. We have in one case, as has Kergin[20] in four, found bronchiectasis in the nonresected superior division of a lower lobe considered normal prior to resection of the basal segments. This required another operation for removal of the remaining superior segment. Further experience may show that segmental pulmonary resection should be applied with caution in cases of chronic suppurative disease, that it should be reserved (except insofar as the lingula is concerned) primarily for bilateral cases wherein maximum conservation of lung tissue is essential (fig. 5).

Segmental resection is applicable in types of chronic suppurative disease other than bronchiectasis, including some cases of lung abscess, infected lung cyst, empyema with bronchopleural fistula and extrapulmonary cyst with bronchocystic fistula and secondary suppuration.

In pulmonary tuberculosis segmental resection is finding wider applicability as the hazards are more readily avoided or controlled. It is impossible at present to itemize the indications for segmental resection in pulmonary tuberculosis. Indications for lobectomy and pneumonectomy have come to be fairly well accepted in the past few years. In general, those for segmental resection will include the same types of tuberculous pathological change, but selection of cases should be much more rigid until it may be shown that the risk is no greater, the results as good. Segmental resection, in the meantime, should receive special consideration in patients for whom maximum conservation of pulmonary function and volume is important or obligatory, e. g., those who have had previous collapse therapy or resection (figs. 4, 6 and 7) and others with distinctly reduced respiratory function. We have also performed segmental resections when localized caseous disease was found incidental to performing a pulmonary decortication for nonexpandable lung under a pneumothorax or tuberculous empyema. In seven of our series segmental resection was performed after previous thoracoplasty on the same side had failed to control the disease. When persistent upper lobe cavitation, after thoracoplasty, requires resection gross involvement may be found in the superior division of the lower lobe. We have sometimes considered it best to resect this segment along with the upper, and perhaps the middle, lobe, conserving the basal segments for space filling if they were not significantly involved (fig. 7).

[20] Kergin, F. G.: The Surgical Treatment of Bilateral Bronchiectasis, J. Thoracic Surg. **19**: 257 (Feb.) 1950.

In no case of pulmonary tuberculosis can it be assumed that all unstable tuberculous lung lesions are being eradicated by pulmonary resection. The other lung also harbors disease that may not be clinically demonstrable. Resection, when elected, should be directed toward those lesions that have failed to respond to, or that are unlikely to be controlled by, less radical procedures and those in which control by other methods would involve very much greater and excessive permanent functional loss. There has been a tendency to resect whole lobes or lungs simply because the tuberculous lesions demonstrable by x-ray or exploration are not localized. However, it seems reasonable that lesions that require resection may be resected segmentally (or even locally in rare instances), and that remaining lesions may heal, as they were wont to do before excisional therapy came into wider use, with the aid of other available measures.

Streptomycin and paraaminosalicylate have helped greatly in making pulmonary resection the procedure of choice in many cases of pulmonary tuberculosis. We use them routinely for variable periods before and after surgery, and it is generally accepted that they have gone far toward eliminating the serious complications that occurred too often before they were available. Resection still should not be entertained as an optional type of treatment in pulmonary tuberculosis. But, it has been established as a type of therapy that in some cases offers the only prospect of cure.

Segmental resection has been used also in certain patients with mycotic lung disease (coccidioidomycosis).[21] It may be indicated in spontaneous pneumothorax,[22] localized emphysema or cystic disease with or without a fistula,[23] pulmonary arteriovenous aneurysm, broncholithiasis,[24] a foreign body in the bronchus and lung trauma. In bronchopulmonary neoplasia, whether benign or malignant, subtotal resection of a lobe or lung is rarely advisable. It may be considered for benign tumors, including hamartoma, and possibly for metastatic malignancy.

TECHNICAL CONSIDERATIONS

The preoperative preparation, anesthesia and postoperative management of patients undergoing segmental resection are essentially the same as for patients undergoing lobectomy. They will not be discussed in detail here.

It would appear that Overholt and associates [16c] have devoted the most time, thought and effort to developing and expounding a standard technique for segmental pulmonary resection. The following points that they have emphasized deserve special mention: (1) The segmental artery, bronchus and vein (if present) should first be isolated at the hilus; (2) intersegmental veins should be identified and preserved; (3) application of clamps across lung tissue should be avoided, and (4) an attempt to cover the raw lung surfaces remaining after segmental resection by bringing together the edges of the visceral pleura is unnecessary and generally inadvisable, since it diminishes lung volume and function by constricting a portion of the lung. The technique that we are using, and which incorporates all the above points, will be described. It has not been altered appreciably since January 1946. Prior to that clamps were placed across lung tissue, after division of bronchus and artery, in five of the cases reported here. The reader is referred to figures 1, 2 and 3, which illustrate the anatomy and the technique employed in resection of the superior segment of the lower lobe of the left lung.

Dissection of the lung segment or segments to be removed is begun near the hilus after identifying the bronchus by palpation. When the segmental artery and bronchus have been exposed the latter is isolated and temporarily occluded while the lung is deflated. The anesthetist is then asked to increase the intratracheal pressure, and the portion of the lung supplied by the occluded bronchus will usually remain collapsed while the remainder of the lung becomes aereated. Thus the segment or segments supplied by the occluded bronchus can be delineated with accuracy. Sometimes occlusion of a bronchus fails to prevent inflation of the lung beyond, since the anesthetic gases may enter it via interalveolar communications (pores of Kohn) with adjoining segments. However, this is not likely to occur when there is extensive pathological change present. When it does occur delineation may be possible by the reverse procedure, i. e., the lung distal to the occluded bronchus may remain aereated when adjoining segments are al-

lowed to collapse. These maneuvers, when succcessful, help to determine whether or not the part of the lung supplied by the occluded bronchus contains all the disease process that is to be extirpated. Delineation of the segment to be resected also permits incision of the visceral pleura along the borders so delineated before dissection in the intersegmental plane is completed. It is not necessary or desirable to do this as a rule, but in difficult situations it may facilitate the dissection. In any case, localization and dissection in the intersegmental plane is more readily accomplished if the limits of the segment can first be outlined.

It is advisable to occlude the bronchus as early as possible in order to entrap and prevent the spillage of infected secretions. The bronchus can then be divided between clamps and by gentle traction on the distal clamp the corresponding segmental artery, which parallels the bronchus, will be readily identified as it is placed on stretch. To improve exposure of the bronchus it is sometimes helpful to ligate and divide the segmental branch of the pulmonary artery first. As traction is maintained on the bronchus the intersegmental plane is developed by blunt finger dissection. When the intersegmental vein can be identified near the hilus it serves as an excellent guide to the plane of dissection. Segmental veins are ligated and divided as they are encountered. Intersegmental veins receive tributaries from the adjoining segment as well as from the segment to be removed. In order to avoid postoperative engorgement of nonresected adjoining segments, the intersegmental veins should be carefully preserved, dividing only tributaries from the segment that is removed.

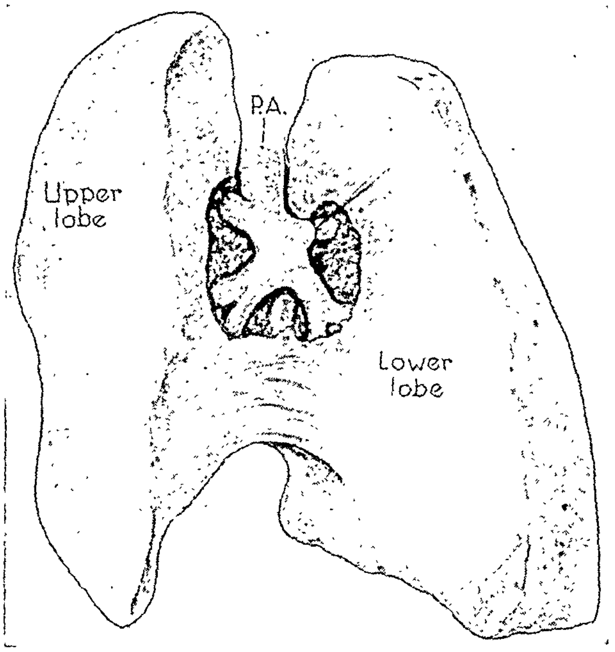

Fig. 2.—Drawing of the left lung showing the hilar anatomy with a dissection over the pulmonary artery at the base of the interlobar fissure. The branch of the pulmonary artery to the superior segment of the lower lobe of the left lung has been ligated.

As blunt dissection in the intersegmental plane is extended to the visceral pleura, the latter is divided as it is reached. If during dissection it is discovered that the disease process extends into an adjoining segment, it may prove advisable to resect the adjoining segment or a subsegment at the same time and according to the same technique. Occasionally a small extension into the periphery of an adjoining segment requires only local excision.

After segmental resection there generally will be small air leaks from the raw surface of the remainder of the lobe, though sometimes there are none at all. Most of these small leaks seal spontaneously before or soon after the operation is completed. If positive pressure anesthesia demonstrates vigorous bubbling from one or more sites on the raw surface of the expanding lung, such leaks should be controlled by clamping and ligation or by application of small mattress sutures of fine silk. Persistent bleeding points from torn tributaries of the intersegmental vein are likewise clamped with fine forceps and ligated.

Finally, the stump of the segmental bronchus is closed after ascertaining that it has been divided as close to its origin as possible so as to avoid leaving a blind bronchial pouch. For closure of a bronchial stump we prefer to use interrupted sutures of 0.017 cm. (0.007 in.) tantalum wire on atraumatic needles, believing that this material has the following advantages: (1) It is nonabsorbable and has tensile strength high in proportion to its fine size, and is thus likely to remain in place while healing occurs; (2) the nonreactive nature of the material and the small caliber of the needle perforations reduce local inflammatory reaction to a minimum; (3) cotton or silk sutures, by capillary attraction, may act like wicks, carrying infected secretions from the lumen of the bronchus deep into the tissues, increasing the danger of inflammation, ulceration and rupture of the stump, and (4) the tantalum sutures are clearly visualized on postoperative roentgenograms, thus making it possible to demonstrate whether or not the suture line remains intact. The tantalum wire sutures are placed before removing the clamp from the stump of the bronchus. While an assistant supports them to maintain closure of the stump, the sutures are individually tied. With one or more of these same sutures, or with fine atraumatic chromic surgical gut sutures, the stump is then buried by sewing onto it a flap of pleura, lymph nodes or other available tissue.

When resecting part of a lung that is collapsed, or which previously has been collapsed, by an artificial pneumothorax, pleural effusion or empyema, a constricting fibrinous membrane is likely to be found over the surface of the lung and, not infrequently, the lung surface is found to be deeply infolded. In such circumstances it is important to decorticate thoroughly all portions of the lung that are to be preserved. By separating adhesions between opposing surfaces of visceral pleura the infolded portion of the lung can be released and considerable lung volume regained.

Generally, in segmental resections the nonresected portions of the lung will now have sufficient volume to permit postoperative filling and obliteration of the pleural cavity without excessive compensatory changes having to occur. Occasionally, however, it may seem advisable to decrease the size of the thorax by performing a partial thoracoplasty. Thoracoplasty in conjunction with resection is most frequently indicated in patients with pulmonary tuberculosis and when the volume of the lung has been considerably reduced by disease and by resection, especially when all or part of an upper lobe has been resected. Thoracoplasties generally have been performed two or more weeks after the resection in these cases. If a thoracoplasty appears advisable we prefer to perform it immediately after the resection, and the following modification in our operative approach has proved advantageous.

Usually we perform a thoracotomy by resecting a long segment of the fifth, sixth, or seventh rib, incising through its periosteal bed. When a thoracoplasty is planned to follow a resection, we first resect only a short posterior segment of the fourth rib and carry the thoracotomy incision from this rib bed anteriorly along the fourth intercostal space. If additional rib resection is advisable to improve exposure the posterior one third of the third rib is removed. On completion of the lung resection all or most of the first and second ribs are easily resected; and the extent of the thoracoplasty can be adjusted to the needs of the case without significantly prolonging the operation. But, if the operative procedure has been long or if the patient's condition is not entirely satisfactory the rest of the thoracoplasty is deferred and completed at a later date. We do not consider it wise to include more than five ribs in a thoracoplasty performed immediately after resection. When a more extensive thoracoplasty is required additional rib segments can be resected, generally under local anesthesia, two or three weeks later. We have performed a five rib thoracoplasty immediately after segmental resection in one case and four rib thoracoplasties, according to this technique, in three. In one of the latter segments of two additional ribs were resected later. In a larger series of patients we have performed thoracoplasty immediately after lobectomy or pneumonectomy, and in only one case has the thoracoplasty appeared to have had a deleterious effect on the patient's postoperative course. In this instance an eight rib throacoplasty was performed immediately after a pneumonectomy, and temporary respiratory embarrassment resulted from excessive paradoxical movement of the chest wall.

Before completion of the operation it sometimes appears desirable to prevent postoperative dislocation and torsion of remaining lung segments by placing a few interrupted surgical gut sutures across anatomic or artificially developed fissures in order that the normal relationships between lung segments will be maintained. It is our practice then to irrigate and cleanse the pleural cavity, to place drainage tubes (if they are to be used) and to introduce antibiotic solutions before the chest wall is closed. Before closure it is also important that the anesthetist expand the remaining portion of the lung in order to be sure that all segments become well aereated. During closure lung expansion is maintained by the anesthetist and by means of suction applied to an intercostal drainage tube or to a catheter introduced through the wound and withdrawn shortly before closure is complete.

Contrary to accepted principles, we have not used drainage tubes routinely in cases of subtotal pneumonectomy. It has been our impression that, after segmental resection, patients in whom some air, blood and exudate are allowed to accumulate around a partially collapsed remaining portion of the lung are less likely to have persistent air leaks and fistula formation. Deposition of fibrin over the bronchial stumps and raw surfaces of a partially collapsed lung may promote early sealing and decrease the danger of fistulas. In some of the patients managed in this way no thoracenteses were required, because there was no significant accumulation of air or fluid in the pleural cavity. In most patients, however, one or more thoracenteses have been performed, beginning on the first or second postoperative day. Optimum lung expansion appears to have been obtained as regularly in these patients as in those in whom pleural drainage has been instituted at the time of operation. In most of our cases we have used one or two intercostal drainage tubes, connecting these to water seal bottles. The tubes are not removed until all leakage of air has ceased and drainage has become serous in character and negligible in quantity (usually within 48 to 72 hours). Motor suction has seldom been applied to these tubes except at the time of their removal. We have omitted drainage tubes in 10 of 50 segmental resections, and in none of these has postoperative bronchopleural fistula or empyema developed. It is true, however, that tubes have been omitted only when very little air leakage, bleeding and exudation were anticipated, which no doubt contributed to the favorable results in this small group.

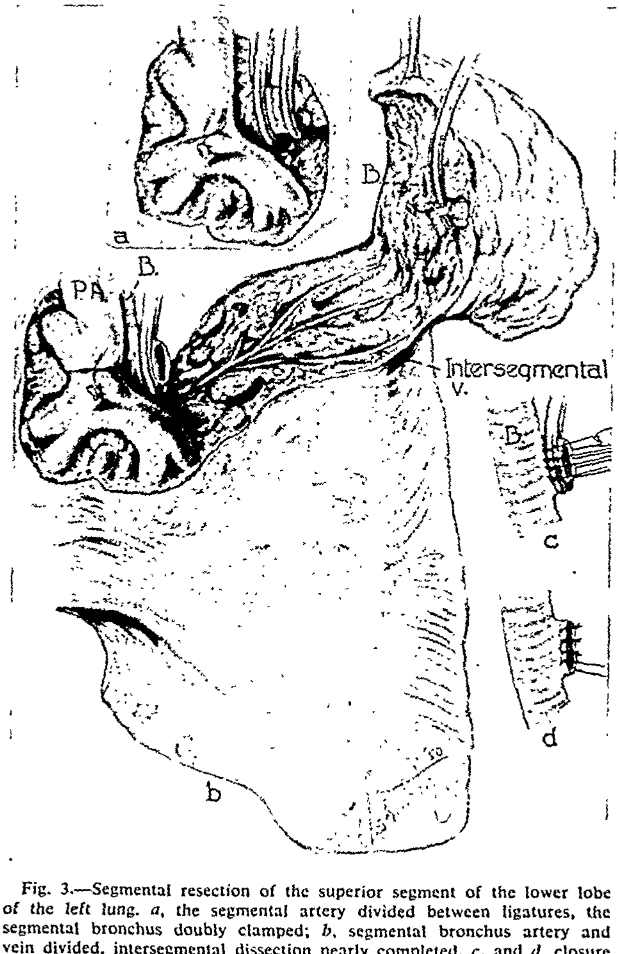

Fig. 3.—Segmental resection of the superior segment of the lower lobe of the left lung. *a*, the segmental artery divided between ligatures, the segmental bronchus doubly clamped; *b*, segmental bronchus artery and vein divided, intersegmental dissection nearly completed, *c*. and *d*, closure of the bronchial stump with interrupted tantalum wire sutures.

lowed to collapse. These maneuvers, when succcessful, help to determine whether or not the part of the lung supplied by the occluded bronchus contains all the disease process that is to be extirpated. Delineation of the segment to be resected also permits incision of the visceral pleura along the borders so delineated before dissection in the intersegmental plane is completed. It is not necessary or desirable to do this as a rule, but in difficult situations it may facilitate the dissection. In any case, localization and dissection in the intersegmental plane is more readily accomplished if the limits of the segment can first be outlined.

It is advisable to occlude the bronchus as early as possible in order to entrap and prevent the spillage of infected secretions. The bronchus can then be divided between clamps and by gentle traction on the distal clamp the corresponding segmental artery, which parallels the bronchus, will be readily identified as it is placed on stretch. To improve exposure of the bronchus it is sometimes helpful to ligate and divide the segmental branch of the pulmonary artery first. As traction is maintained on the bronchus the intersegmental plane is developed by blunt finger dissection. When the intersegmental vein can be identified near the hilus it serves as an excellent guide to the plane of dissection. Segmental veins are ligated and divided as they are encountered. Intersegmental veins receive tributaries from the adjoining segment as well as from the segment to be removed. In order to avoid postoperative engorgement of nonresected adjoining segments, the intersegmental veins should be carefully preserved, dividing only tributaries from the segment that is removed.

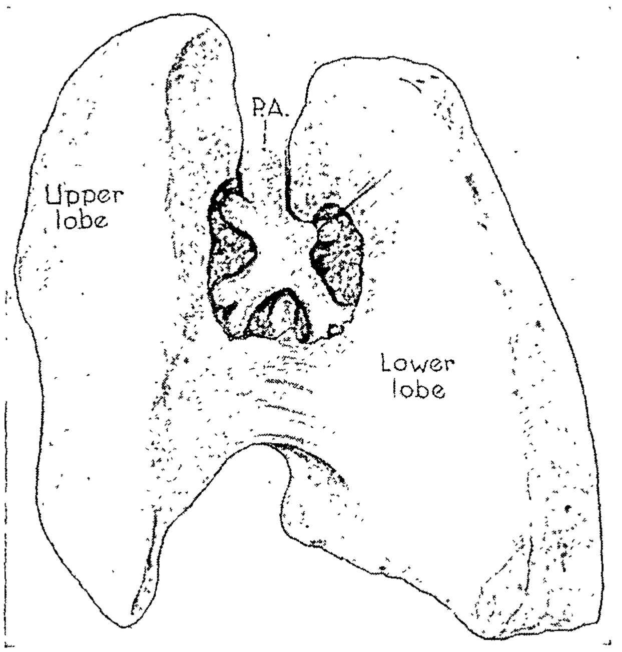

Fig. 2.—Drawing of the left lung showing the hilar anatomy with a dissection over the pulmonary artery at the base of the interlobar fissure. The branch of the pulmonary artery to the superior segment of the lower lobe of the left lung has been ligated.

As blunt dissection in the intersegmental plane is extended to the visceral pleura, the latter is divided as it is reached. If during dissection it is discovered that the disease process extends into an adjoining segment, it may prove advisable to resect the adjoining segment or a subsegment at the same time and according to the same technique. Occasionally a small extension into the periphery of an adjoining segment requires only local excision.

After segmental resection there generally will be small air leaks from the raw surface of the remainder of the lobe, though sometimes there are none at all. Most of these small leaks seal spontaneously before or soon after the operation is completed. If positive pressure anesthesia demonstrates vigorous bubbling from one or more sites on the raw surface of the expanding lung, such leaks should be controlled by clamping and ligation or by application of small mattress sutures of fine silk. Persistent bleeding points from torn tributaries of the intersegmental vein are likewise clamped with fine forceps and ligated.

Finally, the stump of the segmental bronchus is closed after ascertaining that it has been divided as close to its origin as possible so as to avoid leaving a blind bronchial pouch. For closure of a bronchial stump we prefer to use interrupted sutures of 0.017 cm. (0.007 in.) tantalum wire on atraumatic needles, believing that this material has the following advantages: (1) It is nonabsorbable and has tensile strength high in proportion to its fine size, and is thus likely to remain in place while healing occurs; (2) the nonreactive nature of the material and the small caliber of the needle perforations reduce local inflammatory reaction to a minimum; (3) cotton or silk sutures, by capillary attraction, may act like wicks, carrying infected secretions from the lumen of the bronchus deep into the tissues, increasing the danger of inflammation, ulceration and rupture of the stump, and (4) the tantalum sutures are clearly visualized on postoperative roentgenograms, thus making it possible to demonstrate whether or not the suture line remains intact. The tantalum wire sutures are placed before removing the clamp from the stump of the bronchus. While an assistant supports them to maintain closure of the stump, the sutures are individually tied. With one or more of these same sutures, or with fine atraumatic chromic surgical gut sutures, the stump is then buried by sewing onto it a flap of pleura, lymph nodes or other available tissue.

When resecting part of a lung that is collapsed, or which previously has been collapsed, by an artificial pneumothorax, pleural effusion or empyema, a constricting fibrinous membrane is likely to be found over the surface of the lung and, not infrequently, the lung surface is found to be deeply infolded. In such circumstances it is important to decorticate thoroughly all portions of the lung that are to be preserved. By separating adhesions between opposing surfaces of visceral pleura the infolded portion of the lung can be released and considerable lung volume regained.

Generally, in segmental resections the nonresected portions of the lung will now have sufficient volume to permit postoperative filling and obliteration of the pleural cavity without excessive compensatory changes having to occur. Occasionally, however, it may seem advisable to decrease the size of the thorax by performing a partial thoracoplasty. Thoracoplasty in conjunction with resection is most frequently indicated in patients with pulmonary tuberculosis and when the volume of the lung has been considerably reduced by disease and by resection, especially when all or part of an upper lobe has been resected. Thoracoplasties generally have been performed two or more weeks after the resection in these cases. If a thoracoplasty appears advisable we prefer to perform it immediately after the resection, and the following modification in our operative approach has proved advantageous.

Usually we perform a thoracotomy by resecting a long segment of the fifth, sixth, or seventh rib, incising through its periosteal bed. When a thoracoplasty is planned to follow a resection, we first resect only a short posterior segment of the fourth rib and carry the thoracotomy incision from this rib bed anteriorly along the fourth intercostal space. If additional rib resection is advisable to improve exposure the posterior one third of the third rib is removed. On completion of the lung resection all or most of the first and second ribs are easily resected; and the extent of the thoracoplasty can be adjusted to the needs of the case without significantly prolonging the operation. But, if the operative procedure has been long or if the patient's condition is not entirely satisfactory the rest of the thoracoplasty is deferred and completed at a later date. We do not consider it wise to include more than five ribs in a thoracoplasty performed immediately after resection. When a more extensive thoracoplasty is required additional rib segments can be resected, generally under local anesthesia, two or three weeks later. We have performed a five rib thoracoplasty immediately after segmental resection in one case and four rib thoracoplasties, according to this technique, in three. In one of the latter segments of two additional ribs were resected later. In a larger series of patients we have performed thoracoplasty immediately after lobectomy or pneumonectomy, and in only one case has the thoracoplasty appeared to have had a deleterious effect on the patient's postoperative course. In this instance an eight rib throacoplasty was performed immediately after a pneumonectomy, and temporary respiratory embarrassment resulted from excessive paradoxical movement of the chest wall.

Before completion of the operation it sometimes appears desirable to prevent postoperative dislocation and torsion of remaining lung segments by placing a few interrupted surgical gut sutures across anatomic or artificially developed fissures in order that the normal relationships between lung segments will be maintained. It is our practice then to irrigate and cleanse the pleural cavity, to place drainage tubes (if they are to be used) and to introduce antibiotic solutions before the chest wall is closed. Before closure it is also important that the anesthetist expand the remaining portion of the lung in order to be sure that all segments become well aereated. During closure lung expansion is maintained by the anesthetist and by means of suction applied to an intercostal drainage tube or to a catheter introduced through the wound and withdrawn shortly before closure is complete.

Contrary to accepted principles, we have not used drainage tubes routinely in cases of subtotal pneumonectomy. It has been our impression that, after segmental resection, patients in whom some air, blood and exudate are allowed to accumulate around a partially collapsed remaining portion of the lung are less likely to have persistent air leaks and fistula formation. Deposition of fibrin over the bronchial stumps and raw surfaces of a partially collapsed lung may promote early sealing and decrease the danger of fistulas. In some of the patients managed in this way no thoracenteses were required, because there was no significant accumulation of air or fluid in the pleural cavity. In most patients, however, one or more thoracenteses have been performed, beginning on the first or second postoperative day. Optimum lung expansion appears to have been obtained as regularly in these patients as in those in whom pleural drainage has been instituted at the time of operation. In most of our cases we have used one or two intercostal drainage tubes, connecting these to water seal bottles. The tubes are not removed until all leakage of air has ceased and drainage has become serous in character and negligible in quantity (usually within 48 to 72 hours). Motor suction has seldom been applied to these tubes except at the time of their removal. We have omitted drainage tubes in 10 of 50 segmental resections, and in none of these has postoperative bronchopleural fistula or empyema developed. It is true, however, that tubes have been omitted only when very little air leakage, bleeding and exudation were anticipated, which no doubt contributed to the favorable results in this small group.

CLINICAL MATERIAL

We have performed 50 segmental resections, either alone or in conjunction with lobectomy, in 48 patients since 1944. The indication for surgery was pulmonary tuberculosis in 25, bronchiectasis in 17, chronic lung abscess in two and, in one each, the following: teratodermoid cyst with bronchocystic communication and secondary suppuration, bronchopulmonary suppuration secondary to a foreign body (tooth) in a bronchus, ruptured emphysematous bleb with persistent fistula and pulmonary arteriovenous aneurysm. In two of the patients with bronchiectasis bilateral segmental resections were performed. We have used the term "segmental resection" to include removal of the lingula and of a superior segment of the lower lobe, although it has been suggested [25] that these portions of the lung should be regarded as individual lobes. Actually, the absence of well defined fissures makes the technical aspects of the surgery and the hazards identical with those encountered when resecting other bronchopulmonary segments.

COMPLICATIONS

Reluctance to perform segmental resection has been engendered by the fact that postoperative complications, especially bronchopleural fistula and empyema, occur more frequently than after lobar resections. It is almost inevitable that these complications will occur more frequently when a part of a lobe is removed, since there is left a raw lung surface that may be infected and that may present leakage from small openings in direct communication with bronchi. Obviously, greater contamination of the operative field is to be expected. Overholt and his colleagues [16] have shown that the incidence of these complications after segmental resection has been markedly reduced as the techniques have been improved and standardized. Furthermore, these complications generally respond quite promptly to proper management. While the immediate postoperative morbidity tends to be increased, this disadvantage appears to be offset by preservation of maximum lung volume and function and by the fact that segmental resection may offer some prospect of eradicating the disease in certain patients (particularly those with bilateral bronchiectasis) who otherwise would not be candidates for surgical cure, because they could not tolerate resection of all of each lobe that is involved. Other complications which may or may not occur more frequently after segmental resection than after lobectomy include engorgement of adjoining pulmonary segments (particularly when the intersegmental vein is interrupted [26]), incomplete or delayed re-expansion of the remainder of the lung, homolateral or contralateral spread of infection (particularly tuberculous) and atelectasis. Obstructive atelectasis, as pointed out by Churchill,[5] may be due to inflammatory edema in a bronchus adjoining one that has been amputated. Avoiding trauma and the use of tantalum wire sutures may reduce the incidence of this complication. Complications encountered in our series of 50 segmental resections are summarized in the table.

Summary of Segmental Pulmonary Resections

			Complications		
	Number of Cases	Number of Operations	Broncho-*pleural* Fistula with Empyema	Miscellaneous	Death
Pulmonary tuberculosis	25	25	2	1 contralateral spread	1
Bronchiectasis..........	17	19	3	1 transient pulmonary insufficiency 1 lung abscess 1 atelectasis	0
Miscellaneous..........	6	6	0	0	
Total.................	48	50	5	4	1

CHRONIC SUPPURATIVE DISEASE

We have performed 23 segmental resections in 21 patients with chronic suppurative disease. In 19 of these operations (17 patients) the indication was bronchiectasis alone; in two the indication was chronic lung abscess with associated bronchiectasis; in one, secondarily infected teratodermoid cyst with a bronchocystic communication and associated chronic suppuration and bronchiectasis in the basal segments of the lower lobe of the right lung, and in another a tooth lodged in the posterior basal branch of the right lower lobe bronchus with secondary suppuration distal to the obstruction.

The 21 patients included 15 women and six men, and the age range was from 10 to 46 years. The 23 operations involved resection of 37 segments or groups of segments and one subsegment. Lobectomy was performed simultaneously in 10, bilobectomy in one. Entire lobes resected included the following: upper lobe of the right lung, two; middle lobe of the right lung, five; lower lobe of the right lung, one, and lower lobe of the left lung, four. While 12 of these patients had bilateral bronchiectasis, contralateral lobectomy or segmental resection has been performed, to date, in only three.

Bronchopleural fistula and empyema occurred in three patients in this group, each of whom had bilateral bronchiectasis. In two cases this complication followed a second operation, contralateral resection having been previously performed. Two of the three empyemas responded promptly to open drainage, with obliteration of the empyema space and closure of the fistula. The third is our most recent case, and open drainage is still being maintained. Atelectasis complicated the convalescence of one patient who would not, or could not, expel secretions voluntarily after surgery. This responded to bronchoscopic aspiration performed on three occasions. A small abscess (loculated empyema?) developed in the region of the remaining superior segment of the lower lobe of the left lung after resection of its basal segments along with the lingula. The lesion responded to antibiotic therapy alone.

All the patients with bronchiectasis herein reported are considered to have improved since their surgery, though at least nine still have bronchiectasis on the contralateral side. It is possible that patients with bronchiectasis who have had segmental resections are less likely to be relieved completely of their symptoms than those who have been considered good candidates for cure by lobectomy, particularly unilateral lobectomy. However, patients with severe bronchiectasis can be greatly improved, even if they cannot be cured, by elimi-

nation of the more severely involved bronchopulmonary segments. Segmental resection makes rehabilitation available to many patients who formerly were not considered candidates for surgery because of the extent and multilobar distribution of their disease.

PULMONARY TUBERCULOSIS

Twenty-five segmental resections were performed on the same number of patients with pulmonary tuberculosis. There were 13 men and 12 women, their ages ranging from 15 to 58 years. Only once were separate segments resected at the same operation (as contrasted with 13 times in the bronchiectasis group). In one patient a large peripheral tuberculoma in the upper lobe of the right lung was enucleated after resection of the superior segment of the lower lobe of the right lung (fig. 4). While in bronchiectasis the lingula of the upper lobe of the left lung was the segment most often resected (13 times), in tuberculosis a superior segment of a lower lobe most often contained the offending lesion (on the right in 12 instances and on the left in six). A previous resection of the contralateral lower lobe had been performed in one. Homolateral lobectomy was performed at the time of segmental resection in eight, bilobectomy in three. Lobes resected included the upper lobe of the right lung in three, the upper and middle lobes of the right lung in three, the upper lobe of the left lung in four and the lower lobe of the left lung in one.

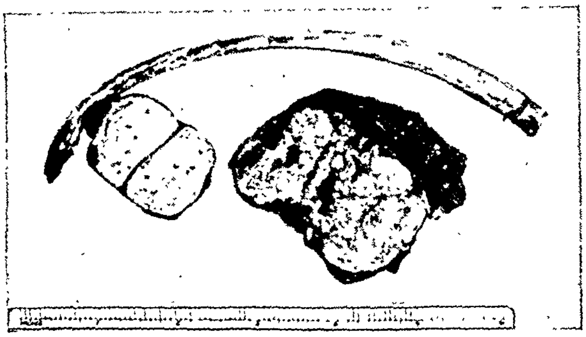

Fig. 4.—Surgical specimens illustrating minimal sacrifice of lung tissue by segmental resection and local excision in E.L., 34 year old diabetic woman with bilateral far advanced pulmonary tuberculosis who failed to have conversion of sputum after bilateral pneumothorax and who was shown to have persistent cavitation in the superior segment of the lower lobe of the right lung by laminagrams. After resection of the superior segment of the lower lobe containing a tuberculoma with central cavitation and enucleation of a subpleural tuberculoma of the upper lobe of the right lung, sputum became negative immediately. Specimen on left shows the incised enucleated tuberculoma of the upper lobe of the right lung; that on the right, the incised superior segment of the lower lobe of the right lung.

Bronchopleural fistula and empyema occurred in two patients after segmental resection for pulmonary tuberculosis. The first of these was a diabetic Negro with cavitation of the lower lobe of the left lung operated on in 1944 before streptomycin was available. Unsuspected tuberculous consolidation of the lingula was found; and this segment was resected, using clamps. A small empyema with a fistula developed, but the patient improved sufficiently to be discharged from the hospital with a negative sputum. However, he died 23 months later with progressive tuberculous disease. This is the only late death in the series. The second patient in whom a bronchopleural fistula and empyema developed had had a lingulectomy to remove a tension cavity that could not be controlled with artificial pneumothorax. Segmental resection was performed because there had been multiple cavities in the lower lobe of the right lung, and it was thought that contralateral resection might eventually be considered. The lingular cavity was extremely adherent to the bronchus passing to the remaining portion of the upper lobe of the left lung. The cavity was ruptured during the dissection, with gross contamination of the pleural cavity. Closed intercostal suction drainage was instituted with early improvement, and sputum conversion occurred; but, a contralateral upper lobe spread appeared after instillation of streptokinase into the small empyema space. While this recent patient is showing steady improvement with continued streptomycin and paraaminosalicylate therapy, her ultimate prognosis cannot be considered good.

Another complication encountered in the tuberculosis cases was severe, though temporary, pulmonary insufficiency. A 58 year old man had a constricting fibrinous membrane, secondary to a previous therapeutic pneumothorax, over the right lung. Decortication was first performed in the hope that pulmonary function might be improved prior to resection of a "tuberculoma" at the apex of the left lung. Improved function was not evidenced by bronchospirometric studies before and after decortication, though radiographically and subjectively the results were good. We proceeded with segmental resection of the apical-posterior segment of the upper lobe of the left lung, which contained a hard tuberculous mass with central caseation necrosis. For several days after surgery the patient appeared critical because of marked dyspnea. He improved gradually and was eventually discharged from the hospital in excellent

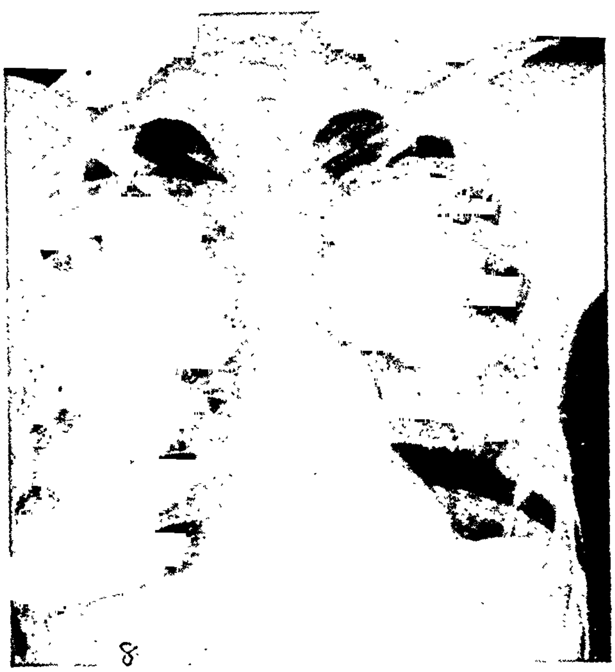

Fig. 5.—K. H., 16 year old boy with severe bilateral bronchiectasis. Chest film following resection of anterior segment of upper lobe of the right lung, the middle lobe of the right lung and the basal segments of the lower lobe of the right lung and later resection of the lingula of the upper lobe of the left lung and the basal segments of the lower lobe of the left lung. Small empyema with bronchopleural fistula following second operation responded promptly to tube drainage. Note tantalum wire sutures.

condition, able to tolerate moderate exertion without discomfort. His sputum was converted immediately after surgery and has remained so.

The only operative death in the 50 segmental resections we have performed occurred after resection of the superior division of a lower lobe of the left lung in a patient with pulmonary tuberculosis. This was an early case, in which clamps were placed across lung tissue to complete the resection. Death was ascribed at autopsy to pulmonary atelectasis, and it is thought that death might have been averted had more prompt and active therapy been administered by the staff. It is worthy of note that two of the four tuberculous patients who had postoperative complications were among the three early patients in whom clamps were used.

Chamberlain[27] has recently reported 75 segmental resections for pulmonary tuberculosis with three deaths and early sputum conversion in 87 per cent. In many of our patients segmental resection was performed, though the risk appeared great, because there seemed to be no alternative prospect of cure. Nevertheless, our only operative death occurred four and one half years ago, when the technique was admittedly poor, and only one of the living patients has not been definitely benefitted as a result of the surgery. In one case we resected only the superior division of the lower lobe of the right lung, because it contained a thick walled cavity, and because the upper lobe of the right lung was essentially free of disease, while the left lung showed considerable involvement. This patient had intermittently positive sputum for five months after his surgery (performed in 1945), after which his sputum remained negative. Only two other patients failed to show sputum conversion immediately after surgery. These are relatively recent cases. Two patients (fig. 6 and the late death) had prompt sputum conversion but became positive again after rather prolonged periods. Three (13 per cent) of the living patients have positive sputum at the present time, the remainder were negative at last report.

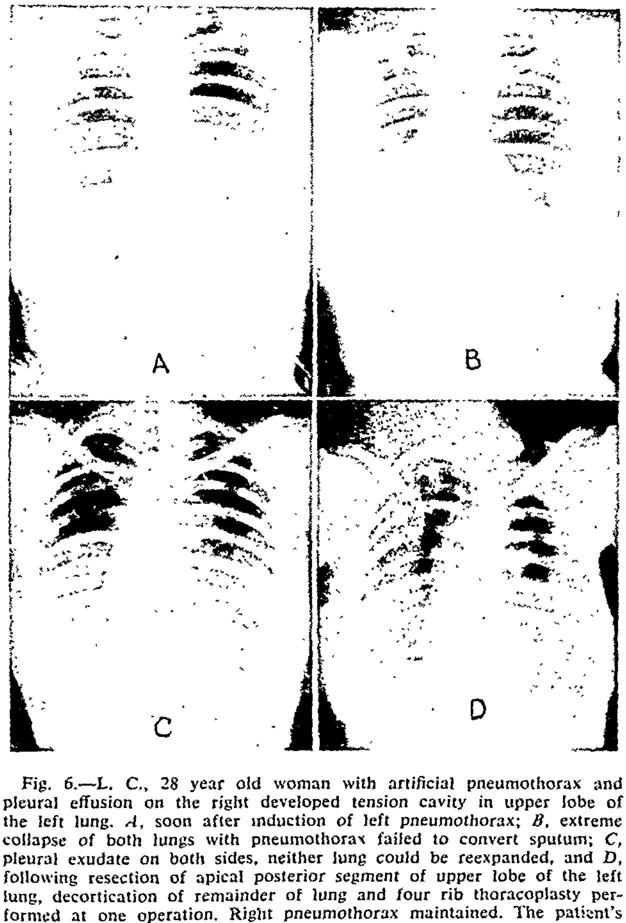

Fig. 6.—L. C., 28 year old woman with artificial pneumothorax and pleural effusion on the right developed tension cavity in upper lobe of the left lung. *A*, soon after induction of left pneumothorax; *B*, extreme collapse of both lungs with pneumothorax failed to convert sputum; *C*, pleural exudate on both sides, neither lung could be reexpanded, and *D*, following resection of apical posterior segment of upper lobe of the left lung, decortication of remainder of lung and four rib thoracoplasty performed at one operation. Right pneumothorax maintained. The patient's sputum converted immediately after surgery, but a recent specimen (about one year after surgery) was reported positive. A similar operative procedure may be performed on the right.

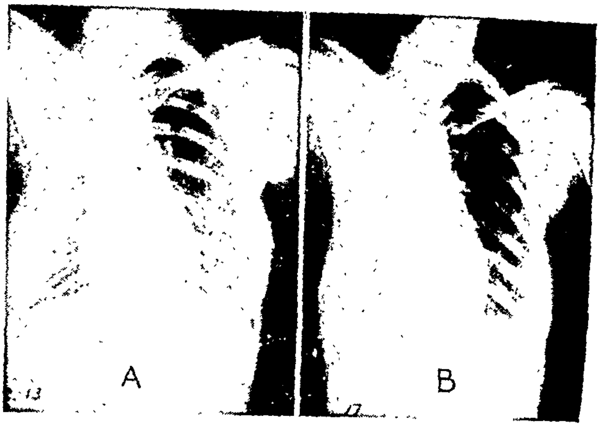

Fig. 7.—T. M., 21 year old woman with far advanced pulmonary tuberculosis whose early response to a nine rib thoracoplasty appeared good, with sputum conversion. *A*, cavity has appeared, opposite third anterior interspace, in superior division of lower lobe of the right lung; cavernostomy was performed and eventually plastic closure of a persistent bronchocutaneous fistula; sputum became intermittently positive and *B*, after resection of the upper lobe of the right lung, middle lobe of the right lung and superior division of lower lobe of the right lung. Sputum now remains negative. The small amount of lung tissue remaining on the right has been sufficient to fill the residual pleural space and prevent mediastinal displacement and over distention of the contralateral lung.

MISCELLANEOUS

We have performed six segmental resections on patients whose primary disease was other than bronchiectasis or tuberculosis, and in four of these, mentioned previously, suppurative disease provided the indication. One patient with a ruptured emphysematous bleb and persistent tension pneumothorax was found to have a

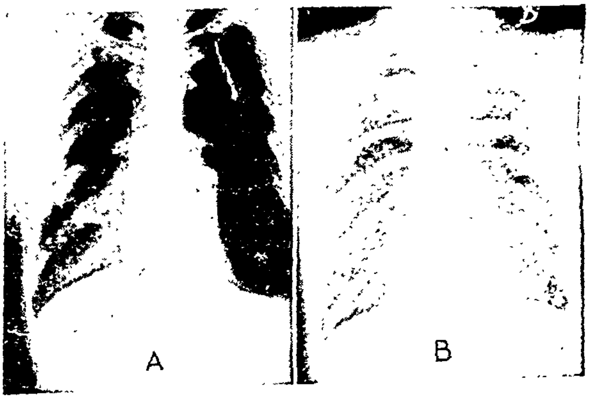

Fig. 8.—E. A., 58 year old man with persistent pneumothorax after rupture of emphysematous bleb (see text). *A*, chest X-ray before surgery, and *B*, after resection of apical-posterior segment of upper lobe of the left lung. There are large emphysematous blebs remaining in the upper lobe of the right lung, but patient is asymptomatic.

large (1 cm.) tear in the bleb at thoracotomy. Resection of the apical-posterior segment of the upper lobe of the left lung, containing multiple blebs, gave an excellent result (fig. 8). The other segmental resection was for pulmonary arteriovenous aneurysm in the superior division of the lower lobe of the right lung. After resection, cyanosis, polycythemia and clubbing gradually disappeared. No complications occurred in the patients on whom we performed segmental resections in this miscellaneous group.

SUMMARY

The lungs are comprised of 18 bronchovascular units, or segments. These segments, where they do not border on fissures, are separated by planes that generally contain no important structures other than intersegmental veins. Dissection along these planes can be accomplished readily, and segments can be removed, singly or in groups, after division of the segmental bronchus, artery and vein (if present) at their origin. When performing segmental resections it is important to preserve the intersegmental veins with the nonresected adjoining segments.

Segmental resection is applicable in some types of bronchopulmonary disease wherein removal of the involved portions of the lung offers the only means for cure or for maximum palliation. Segmental resection is recommended for patients with such extensive involvement that lobar resections would result in excessive reduction in respiratory function. Nonresected portions of a lung have space filling as well as functional value.

Indicated most frequently in bronchiectasis and tuberculosis, segmental resections are also applicable in some cases of lung abscess, mycotic disease, cystic disease, localized emphysema with or without ruptured bleb, bronchopleural or bronchocystic fistula, broncholithiasis, trauma and arteriovenous aneurysm. In bronchopulmonary neoplasia subtotal resection of a lobe or lung is rarely advisable.

Fifty operations are reported in which segmental resection was performed, either alone or in conjunction with lobectomy.

Specialization.—The main justification for specialisation among clinicians is the necessity for mastering difficult techniques. The various branches of surgery are all legitimate specialties for therapeutic reasons; and ophthalmology, otorhinolaryngology, and perhaps a few others are also legitimate for diagnostic reasons. The same considerations apply to anesthetics and radiotherapy. But in the field of medicine as opposed to surgery, and also in the important part of surgery which precedes the actual operation, there is little to be said in favour of specialisation, and much to be said against it. The modern tendency to subdivide physicians into cardiologists, gastroenterologists, phthisologists, diabeticians, rheumatologists, kidney specialists, and the rest is regrettable. Even in so far as certain medical specialties, such as pediatrics and neurology, are justifiable, those who practise them would usually be better if they were also general physicians.

The value of the physician is derived far more from what may be called his general qualities than from his special knowledge. A sound knowledge of the etiology, pathology, and natural history of the commoner disease is a necessary attribute of any competent clinician. But such qualities as good judgment, the ability to see the patient as a whole, the ability to see all aspects of a problem in the right perspective, and the ability to weigh up evidence are far more important than detailed knowledge of some rare syndrome, or even the possession of an excellent memory and a profound desire for learning.—J. W. Todd, M.D., Specialisation, *The Lancet*, Feb. 24, 1951.

CLINICAL NOTES

HEMOLYTIC STREPTOCOCCIC SORE THROAT

CORTISONE IN THE TREATMENT OF THE POSTSTREPTOCOCCIC STATE

Alexander A. Doerner, M.D.,
Charles F. Naegele, M.D.
and
Frederic D. Regan, M.D., New York

Patients suffering from hemolytic streptococcic infection of the respiratory tract frequently develop a variety of disorders as a complication of their illness. Skin manifestations, polyarthritis, involvement of the heart and its structures, persistent fever, general toxicity, and nephritis may develop in from three to 30 days after the respiratory infection begins.

It has been noted [1a] that in approximately 20% of such respiratory tract illnesses, a disorder supervened which could not be explained on the basis of increased reaction of the primary inflammatory site or as a result of invasion of remote tissues by the hemolytic Streptococcus. These complicating nonsuppurative sequelae of hemolytic Streptococcus disease have been referred to as the poststreptococcic state. It has been suggested that this state occurs not as the result of the primary etiological agent per se, but rather as a more complex mechanism by which the patient's tissues have been sensitized to some fraction or product of the hemolytic Streptococcus, probably as a result of previous exposure to this organism.

It is the purpose of this paper to present a case demonstrating the classical features of the poststreptococcic state as described by previous investigators,[1] and to emphasize the efficacy of cortisone in the treatment of this condition.

REPORT OF CASE

History.—L. S., a 17 year old white woman of Latvian extraction, was admitted to the United States Marine Hospital, Staten Island, N. Y., April 24, 1950, with a history of sudden onset of a sore throat, chills and fever six days previously. A diagnosis of acute tonsillitis had been made by her physician, and penicillin therapy initiated. Because of lack of clinical response and continued fever to 104 F., she was referred for hospitalization. The past history was noncontributory.

Physical Examination.—On admission, examination revealed an acutely ill, toxic young woman, with a marked erythematous bimalar flush. The temperature was 104 F., pulse 126 per minute, respirations 24 per minute. The posterior pharyngeal wall and tonsillar fossae were diffusely injected, and there were sev-

eral small ulcerations on the undersurface of the tongue and on the buccal mucosa. There was a scarlatiniform rash involving the trunk, noted especially on the extremities and back. There was a bilateral, nontender, cervical adenopathy. The remainder of the examination disclosed no pertinent abnormal findings.

Laboratory Data.—Examination of the blood showed 3,400,000 red cells, 10.5 gm. of hemoglobin per 100 cc., 27,100 white cells, with 39% band forms, 49% neutrophiles, 10% lymphocytes and 2% eosinophiles. Platelet count, bleeding time and coagulation time were normal. The sedimentation rate (Cutler method) was 25 mm. in one hour. Urinalysis was negative. Agglutination reactions for typhoid, paratyphoid, Brucella, and Bacillus proteus X_{19} form O were negative in all dilutions, and remained so throughout hospitalization. The heterophile agglutination tests were repeatedly negative. The antistreptolysin titer was initially positive in a dilution of 1:40, rising to 1:450 on the 25th hospital day. Stool examinations were negative for ova, parasites and pathogenic bacteria. Initial blood culture revealed colonies of gram-positive cocci, which could not be subcultured. Subsequent blood cultures, repeated at frequent intervals, were consistently negative. Roentgenograms of the chest were normal. The interpretation of the electrocardiogram was within normal limits. Smears and cultures of the throat demonstrated the presence of beta hemolytic streptococci. All subsequent throat cultures were negative.

The clinical impression was that the patient had a hemolytic streptococcic sore throat, resistant to previous penicillin therapy.

Hospital Course.—On the first hospital day, the oral administration of aureomycin hydrochloride was begun, with a total daily dosage of 4 gm. The patient continued to be febrile and markedly toxic. Because of possible bacteremia, penicillin therapy was also instituted, 1 million units being injected intramuscularly every three hours. Subsequently, the results of sensitivity studies were returned, showing the hemolytic Streptococcus initially isolated to be completely inhibited by 5 units of penicillin per milliliter, 5 γ of aureomycin per milliliter, 5 γ of chloramphenicol (chloromycetin®) per milliliter, 5 γ of streptomycin per milliliter and 2,500 γ of sulfadiazine per milliliter.

Except for the development of an anemia believed to be due to her general toxemia, the patient's course and laboratory findings continued unchanged. On the eighth hospital day, a grade II apical systolic murmur was heard for the first time. Early desquamation of the skin of the hands and feet was also noted to be present.

Aureomycin was discontinued, and the administration of acetylsalicylic acid begun, 20 grains (1.3 gm.) every four hours. Four days later, streptomycin was added to the patient's therapeutic regimen, 2 gm. being given daily, intramuscularly, in divided doses.

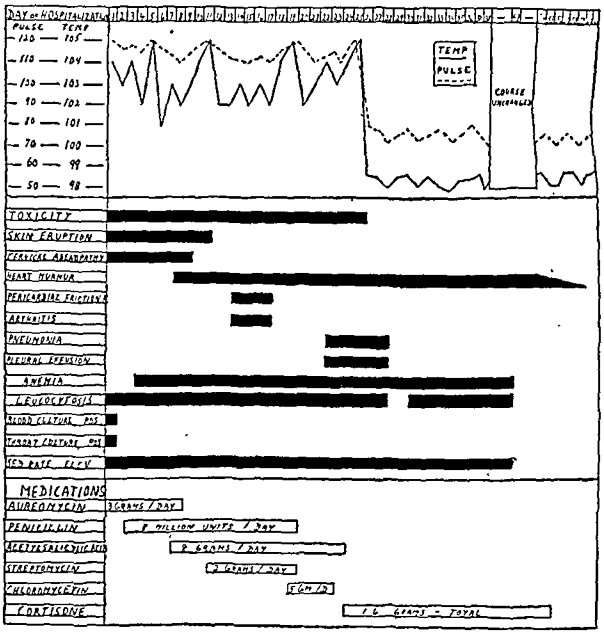
On the 14th hospital day, a pericardial friction rub was heard, and the apical systolic murmur appeared to be more marked. The patient also complained at that time of severe pain in her left knee and right ankle. Slight erythema and moderate effusion of the left knee was present. These manifestations subsided within four days.

On the 20th hospital day, penicillin and streptomycin were discontinued, and chloramphenicol was begun, in a total daily dosage of 5 gm. Three days later, signs of a left lower lobe pneumonia with pleural effusion were detected, and a diagnostic tap obtained straw-colored fluid, which proved to be sterile transudate.

Intensive supportive therapy was maintained, including frequent blood transfusions, electrolyte replacement, parenteral vitamins and general symptomatic measures. Despite this, the patient's course continued downhill. On the 25th hospital day, eosinophile counts showed a significant increase following the epinephrine test.[2] The following day cortisone therapy was initiated.

Four hours after the administration of 100 mg. of cortisone, an eosinopenic response was noted. Within 12 hr., the patient became afebrile, and remained so thereafter. She received a total of 700 mg. of cortisone within a four-day period. She was then maintained on 100 mg. daily for four days, at which time the early manifestations of a Cushing's syndrome were observed; notably, a "moon facies" and plethoric appearance. Serum electrolyte studies revealed the development of a hypokalemic hypochloremic alkalosis. The patient was treated with potassium chloride and testosterone proprionate, with subsequent reversal of these findings. Cortisone therapy was reduced to a daily dosage of 25 mg.

During the first four days of cortisone therapy, the white blood cell count dropped to 7,800, with a normal differential. The sedimentation rate (Cutler method) remained elevated, being 30 mm. in one hour. Two days later, the patient's white blood cell count rose to 17,000, with a marked neutrophilia. Serial counts were consistently in the same range, until the 22nd day of cortisone therapy, when a normal white cell count and differential and a normal sedimentation rate were recorded.



Clinical and laboratory course of L. S.

The patient's course was one of continued marked improvement. Cortisone therapy was discontinued after 28 days of treatment; a total of 1.6 gm. had been given. Ambulation was gradually achieved.

The patient has remained clinically well to date, and all laboratory examinations have been within normal limits.

COMMENT

The essential features of the nonsuppurative complications of hemolytic Streptococcus disease and the importance of the concept of the poststreptococcic state have been emphasized by many investigators[3] in recent years. Rantz and his associates[1a] studied a large number of cases of sore throat caused by group A hemolytic streptococci in young adults. Although complete and uneventful recovery occurred frequently, convalescence in many instances was marred by the development of a complication. These complications included prolonged and persistent fever, general toxicity, skin manifestations, arthritis, adenitis, carditis, pneumonia and glomerulonephritis. In individual cases, there were noted nonsuppurative sequelae, ranging from few to many and varying in intensity from mild transient states to those producing extreme debility. In fatal cases, Mallory and Keefer[1b] described anatomic changes in the heart, kidneys, liver, spleen, lungs and pancreas.

SUMMARY AND CONCLUSIONS

The case presented describes the development in a young white woman of a typical hemolytic Streptococcus infection of the throat. In spite of early and adequate antibiotic therapy, she continued to manifest prolonged unremitting fever. Subsequent complications included a scarlatiniform rash, transient arthritis of the knee and ankle, a grade II mitral systolic murmur, a transient pericardial friction rub, a left lower lobe pneumonia and pleural effusion, anemia, leukocytosis with pronounced neutrophilia, progressive generalized toxicity, and a downhill course leading to extreme debility.

The chart illustrates the clinical and laboratory course of this patient, and her complete lack of response to specific antibiotics, salicylates and general supportive measures. It thus seems evident that this case fulfilled the criteria previously defined for the poststreptococcic state.

After the original observations by Hench[4] and his group, many workers have confirmed the fact that patients with rheumatic fever demonstrate a dramatic improvement when treated with cortisone. Because of the proved ability of cortisone as an agent capable of inhibiting the tissue response of rheumatic fever, it was felt that it should be effective in treating other of the nonsuppurative complications of hemolytic Streptococcus infections. For this reason, cortisone was thus administered to this patient. It was followed immediately by the rapid disappearance of all the features of the poststreptococcic state.

It appears possible that the mechanism of cortisone's favorable influence on the manifestations of the poststreptococcal state depends on the ability of the adrenal oxysteroids to alter the allergic tissue reaction that follows the union of antigen and antibody.[5] This hypothesis would tend to be supported by the work of Mallory and Keefer,[1b] which suggested that the anatomical lesions found in the tissues of fatal cases of hemolytic streptococcal infection were due in part at least to an antigen-antibody reaction.

It has been further emphasized by Selye[6] that certain fundamental hormonal homeostatic mechanisms occur during stress situations. It has been shown experimentally and at least implied clinically that during periods of excessive stress, this hormonal self-regulation breaks down. It is felt that in some of the collagen disorders and related diseases, there exist complex metabolic disturbances, which necessitate prolonged replacement of adrenal steroids, and in certain of these, probably permanent replacement. On the other hand, in states where the "alarm reaction" has been initiated by bacterial infection and where an antigen-antibody relationship exists, in our experience, the process has been reversible.

We would thus agree with Hench, who observed that the action of cortisone appears to be group specific rather than disease specific or nonspecific, and that cortisone perhaps constitutes one of the body's chief defenses against the action of certain agents on certain tissues.

ACTH AND CORTISONE IN THE ACUTE CRISIS OF SYSTEMIC LUPUS ERYTHEMATOSUS

John R. Haserick, M.D.
A. C. Corcoran, M.D.
and
Harriet Dustan, M.D., Cleveland

Management of systemic lupus erythematosus with cortisone or pituitary adrenocorticotropic hormone has now been resolved into two phases: the first consists of the control of the disabling manifestations of the disease with cortisone and pituitary adrenocorticotropic hormone, and the second of a maintenance program that sustains this remission but does not elicit the side effects of hypercorticoidism. The acute lupus crisis, such as is described below, is in some ways a thing apart from either phase and is usually fatal. The purpose of this report is to describe the treatment of the acute lupus crisis with massive doses of cortisone or pituitary adrenocorticotropic hormone.

Sixteen patients with systemic lupus erythematosus have been treated with these drugs at the Cleveland Clinic Hospital since October 1949. In each case the plasma lupus erythematosus test gave positive results. Four patients have died, but none since we have begun the use of the large doses. Four have entered acute lupus crises, either spontaneously or during attempts to withdraw cortisone. All of these were successfully treated with the massive dose technic. One such patient is reported in brief.

REPORT OF CASE

A woman, aged 23, was admitted to the Cleveland Clinic Hospital on Oct. 18, 1950. In October 1948, she noticed sudden onset of pain, swelling and redness of the interphalangeal joints of both hands. Her condition responded to salicylates until January 1949 when the arthritis recurred. A fever of 102 F. developed, and she was hospitalized elsewhere. The diagnosis was rheumatoid arthritis. Gold injections were begun, with gradual improvement in her condition. A complete remission occurred in April 1949, and she returned to work. Joint pains recurred in October 1949. Shortly thereafter a temperature of 104 F. was noted in association with pleural pain and effusion. From the left thoracic cavity, 2.6 liters of fluid were removed. Her condition became steadily worse, requiring frequent hospitalization.

Physical examination revealed an asthenic, pale, orthopneic white woman. The temperature was 102.2 F. and pulse rate 100 per minute. The blood pressure was 90/70 (mm. Hg.). A few shotty nodes were felt in the posterior cervical region. The skin was clear. Examination of the chest revealed dulness of the bases with decreased tactile fremitus. The breath sounds were absent in the left base and diminished on the right. Sinus rhythm was

This investigation was supported (in part) by a research grant from the National Institute of Health, Public Health Service.

noted. The spleen reached one finger's breadth below the costal margin. The neurologic examination was normal.

Laboratory studies revealed hemoglobin to be 8 Gm. per 100 cc. Leukocyte count was 1,500 per cubic millimeter; in the differential count, neutrophils were 51 per cent, lymphocytes 36 per cent and monocytes 13 per cent. The plasma lupus erythematosus test[1] gave positive results. The sedimentation rate (Rourke-Ernstene) was 0.75 mm. per minute (the normal being less than 0.45). There were no total blood eosinophils.[2] Blood chemistry determinations (urea, sugar, serum sodium, potassium, plasma carbon dioxide-combining power and chlorides) were normal. Plasma proteins (electrophoretic technic) totaled 5.97 Gm. per 100 cc., albumin 2.69 Gm., alpha globulin 0.55 Gm., beta globulin 1.22 Gm., gamma globulin 1.18 Gm. and fibrinogen 0.3 Gm. per 100 cc. Urea clearance was 68 per cent of normal. A 12 hour urine specimen taken at night contained protein 1.05 Gm., casts 2,000,000, erythrocytes 1,200,000 and leukocytes 24,000,000.

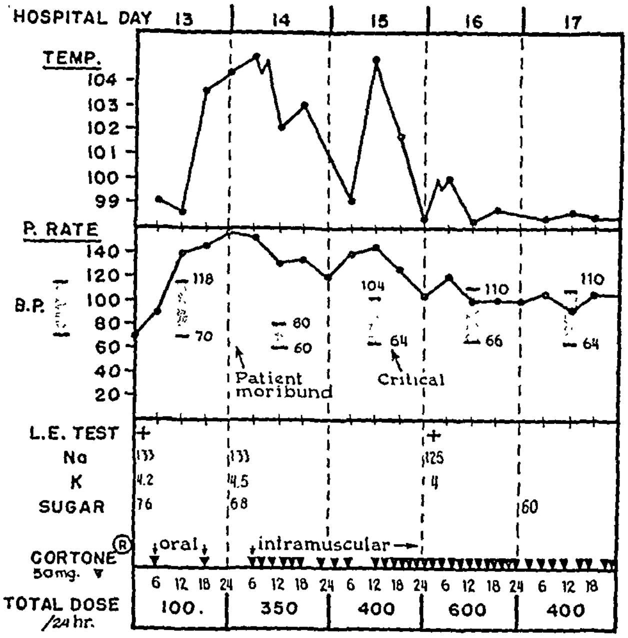

Chart of woman, aged 23, in acute lupus crisis. Note response to cortisone given at two hour intervals. B. P. represents blood pressure (mm. Hg.).

On 200 mg. of cortisone daily the temperature and pulse rate became normal within 48 hours. The drug was administered orally in one-half glass of milk in divided doses of 50 mg. every six hours. Antibiotics were concurrently administered. On the thirteenth hospital day the pulse rate rose from 84 to 140 per minute. In a few hours the temperature rose from 98.8 F. to 105 F., and the patient seemed moribund (chart). Respirations were rapid and shallow. The pleural effusion was greatly increased. The cortisone dosage was increased to 50 mg. given intramuscularly every two hours. A definite improvement was noted within six hours, and after 12 hours the dose was changed to 50 mg. every four hours. After three such doses the patient's condition again became critical, and the two hour regimen was resumed. A total of 600 mg. was administered within 24 hours. Though the clinical improvement was striking, there was no important change in the laboratory findings. The results of the plasma lupus erythematosus test remained positive, and the sodium, potassium and sugar levels were unchanged. Proteinuria decreased. The patient was subsequently started on pituitary adrenocorticotropic hormone and is now clinically well on 40 mg. of pituitary adrenocorticotropic hormone per day.

COMMENT

Acute lupus crises were successfully treated in three other patients. Cortisone was administered in two, and pituitary adrenocorticotropic hormone in one. The short interval, large total dose technic was used in each instance. Aside from our usual precautions, such as low sodium diet, supplementary potassium and antibiotics, no special regimen was followed. In two patients, large doses of cortisone resulted in a decrease in proteinuria, and in one of these a decrease in hematuria occurred. Protein excretion fell from 18 Gm. daily to 4 Gm. in one patient, from 3 Gm. daily to 1 Gm. in the other patient. The urinary abnormalities were not intensified during the lupus crisis in a fourth patient, and massive doses of cortisone did not alter them significantly. After three days of intensive treatment the results of the plasma lupus erythematosus test became negative in one patient. They remained so during several weeks of maintenance steroid therapy but became positive again during a subsequent relapse. In the other three patients the massive doses failed to alter the positive results of the plasma lupus erythematosus tests.

Cortisone and pituitary adrenocorticotropic hormone each have their place in the management of systemic lupus erythematosus. We have previously considered cortisone the slower of the two in inducing a lupus remission. It is now evident that, given orally or intramuscularly in large enough doses, cortisone may produce an even more rapid clinical response than comparable dosages of pituitary adrenocorticotropic hormone. In the management of chronic cases, cortisone given orally is well tolerated and definitely preferred to intramuscular administration by the patients.

On the other hand, it is our experience that pituitary adrenocorticotropic hormone is preferable in the lupus patient with the volatile, stormy course. Relapses during pituitary adrenocorticotropic hormone are less severe and, because they are slower in onset, can be detected before the condition of the patient deteriorates into an acute lupus crisis.

It is not recommended that the short interval, massive total dose technic be used except during the acute lupus crisis when the patient's status is desperate and irresponsive to the usual doses. Most patients in relapse but not in crisis respond to about 200 mg. of either drug per day. When a satisfactory response has been established, the total daily dose is gradually diminished. The aim is to find a minimal level consistent with the patient's well-being. We no longer discontinue the drugs entirely, though an attempt is made to diminish the dose progressively over several months.

The onset of an acute lupus crisis can often be traced to intercurrent infection. Consequently, antibiotics are given in full doses during the acute phase as an adjunct to cortisone and pituitary adrenocorticotropic hormone therapy. They are often continued in smaller, bacteriostatic doses as adjuncts to the maintenance routine.

SUMMARY AND CONCLUSIONS

Sixteen patients with systemic lupus erythematosus have been treated with pituitary adrenocorticotropic hormone and/or cortisone at the Cleveland Clinic Hospital. Both drugs have been found to be invaluable in the control of the acute phase, as well as during the maintenance periods, of the disease. Four patients with acute lupus crises responded favorably to short interval, massive total doses. No untoward clinical or laboratory findings were noted. Such treatment is recommended in these desperate situations. Smaller doses are effective in most patients, and still smaller doses suffice in prolonged management. Thus it seems likely that the need for adrenal hormones varies with the severity of the process.

ADDENDUM

Since this manuscript was submitted, we have observed a girl, 13 years of age, during an acute lupus crisis that did not respond to cortisone in doses of 250 mg. daily.

The crisis was evidenced by severe malaise, high fever, epileptiform convulsions with dysrhythmic electroencephalographic patterns, retinal exudates, proteinuria, cylindruria and hematuria. In spite of antipyretics and tepid sponging, her condition became critical with fever ranging from 100.1 to 104.6 F. on the oral administration of 350 mg. of cortisone daily. Her condition deteriorated further the following day with fever ranging from 100 to 105.6 F. A total cortisone dosage of 900 mg. (given intramuscularly every three hours) resulted in some improvement; her condition was still critical, and her fever was only slightly less the next day on a dosage of 1,050 mg. The dosage was then increased to a total of 2,300 mg. (100 mg. every hour) for one day. Her condition improved greatly, and the next day her temperature ranged only from 98 to 99.8 F. Cortisone dosage was reduced to 1,400 mg. and on succeeding days was further decreased. The patient died two weeks later of an untoward complication.

The partial remission obtained with what we believe to be the largest recorded daily dosages of cortisone illustrates the principle of massive dose therapy in acute lupus crisis.

VINEGAR EEL IN SPUTUM

REPORT OF A CASE

G. Hal DeMay, M.D.
Robert S. Long, M.D.
John R. Schenken, M.D.
and
Eugene E. Simmons, M.D., Omaha

The following brief case report is presented as an illustration of an unusual finding in a routine examination of a sputum specimen.

N. H., a white male manufacturing executive, 50 years of age, was admitted to the hospital March 28, 1950, for investigation of an acute episode of rather profuse hemoptysis. The clinical history revealed that he had had a chronic productive cough since childhood and pulmonary hemorrhage had occurred on two previous occasions. The bronchogram confirmed the clinical diagnosis of extensive saccular bronchiectasis involving chiefly the left lower lobe and the lingula. The rest of the lung fields were roentgenographically normal in appearance. Routine sputum examinations disclosed the presence on one occasion of an organism resembling the larva of Filaria, Strongyloides or hookworm. Inasmuch as a fresh disposable sputum cup was used for each specimen, the organism was not thought to be a contaminant. The question at once arose as to whether the pulmonary pathology could be due to persistent or recurrent infection with one of these organisms. Several fresh stool specimens were examined, and no ova, larvae or adult forms of these organisms were found. On closer examination, the specimen found in the sputum appeared to be much broader than the filaria larva, but the buccal cavity was not well enough preserved to permit differentiation from that of Strongyloides or Necator americanus. It was then suggested that the specimen was probably Anguillula aceti, commonly known as the "vinegar eel." The patient was then questioned, and it was found that he had eaten spinach and vinegar the evening before the sputum cup was collected. Examination of vinegar from the kitchen where the patient had been served disclosed the presence of many vinegar eels identical with the specimen found in the patient's sputum. The patient subsequently underwent left lower lobectomy and lingulectomy. The gross and microscopic pathology were characteristic of chronic saccular bronchiectasis, and no larvae were found in the surgical specimen.

COMMENT

A brief survey of the literature has not revealed a previous report of this unusual finding. It is of interest in that it illustrates how a common nonpathogenic organism may contaminate a laboratory specimen and confuse a clinical diagnosis as to correct etiology.

DIVERTICULUM OF THE STOMACH

REPORT OF A CASE

Norman Van Wezel, M.D., Foley, Ala.

In July, 1948, Bralow and Spellberg reported 26 new cases of diverticulum of the stomach. They also reviewed the 150 previous cases which Moses had covered up to 1946 in his review. This indicates that in the hundreds of thousands of gastrointestinal studies made, there are very few cases of diverticulum of the stomach reported. The small number of cases reported may be due to two things: either an actual rarity of stomach diverticula or the fact that they are overlooked. Since this is the first time that I have seen this condition in private practice, I am therefore reporting this case.

In large clinics diverticulum of the stomach has been reported as occurring in from 0.02% to 0.65% of all gastrointestinal studies. Though diverticula of the gastrointestinal tract may occur in any part of the intestinal tract, the portion of the tract in which they least occur is the stomach. When they occur in the stomach, the most common location is on the lesser curvature on the posterior surface of the cardia. Age incidence or sex difference has not been determined because the cases are too few to tabulate.

The types of diverticula are the congenital, the acquired, and the false. In the congenital type, all three walls of the stomach are within the diverticulum, and the patient is, of course, born with this deformity. Acquired diverticula are divided into two types, the pulsion type and the traction type. The pulsion type is probably due to an ulcerated area with some increase in the intragastric pressure. In the traction type there is some external inflammatory process that produces a local adhesion and pulls the diverticulum externally. A false diverticulum is probably due to some break in the wall, so that there is actually a hernia of the mucosa or the submucosa through the musculature. This is not considered a true diverticulum.

From the Departments of Pathology and Internal Medicine, University of Nebraska College of Medicine and Nebraska Methodist Hospital.

Symptoms of diverticula of the stomach may not be present. Many patients with stomach diverticula are labelled neurotic or psychoneurotic for a long time. In reviewing the cases, it will be found that some diverticula have definitely been proved to produce symptoms, because on the removal of the diverticulum the patient's complaining symptoms were also removed. However, it is probable that most stomach diverticula are asymptomatic. The diagnosis, of course, can be made only by x-ray. It can then be confirmed by surgery or exploration. Diverticula are often difficult to confirm at operation because of the relative degree of inaccessibility of the diverticulum at the time of operation. When the examiner is convinced that the diverticulum is causing symptoms, then surgery is indicated. However, in the case reported below, the patient was completely relieved by proper drainage, which he obtained by lying on his left side immediately after eating. It is because of this incidental finding and the conservative treatment that this case is being reported for the literature.

REPORT OF CASE

W. H. O., a 39 year old white married man, a mechanic by trade, was referred for x-ray examination by Dr. J. M. Michaelson.

His history revealed that throughout his entire life he was sensitive to milk, and he had perennial hayfever. He attributed most of his digestive disturbances to the inadvertent use of milk. However, six months before examination he was found to have undulant fever. After this, bronchitis developed, which was treated by antibiotics, and he then broke out with a generalized rash, which was thought to be due to the antibiotics. Following this, his digestive symptoms, which had always, in the past, been due to milk, returned. This time, however, there had been no ingestion of milk. The indigestion consisted of heartburn, or pyrosis, with a crowding of his heart. There was some nausea but no vomiting and some sharp sticking pains in the region of the right nipple. Belching or ingestion of soda did not give him relief. He now noted that when he had this heartburn he began to break out with some urticaria. This same syndrome, namely, the heartburn, or pyrosis, followed by the urticaria, in the past had been attributed to milk and, occasionally, to simple nervousness. It was with this clinical diagnosis, namely, a gastric neurosis complicated by an allergic state, that he was referred for x-ray studies.

A complete physical examination revealed no abnormalities except a pale boggy nasal mucosa consistent with hayfever. The laboratory studies were all within normal limits, except the examination of the blood smear, which showed 10% eosinophils.

The x-ray examination revealed that the patient had a diverticulum on the posterior surface of the lesser curvature near the cardia of the stomach. This would vary in size. On the most medial surface of the diverticulum there was an irregularity which has not changed.

COMMENT

It is to be emphasized that the diverticulum varies in size, either because of incomplete filling or because of overdistention and contractions. The patient has been completely relieved of all of his symptoms by assuming a left lateral recumbent position immediately after eating. He has had no other therapy except the usual avoidance therapy for his food allergy. Because of its contractibility, it is probably a true diverticulum of the congenital type.

The above case is presented to serve as a record of an unusual condition of the stomach so that it may be tabulated with other studies and, also, to demonstrate the relief of symptoms as obtained by the simple procedure of assuming the proper postural drainage.

CLOSTRIDIUM BOTULINUM IN A FATAL WOUND INFECTION

Joseph B. Davis, M.D., Marion, Ind.
Lida H. Mattman, Ph.D.
and
Marjorie Wiley, A.B., Philadelphia

Clostridium botulinum has been studied extensively because of its power to cause a fatal type of food poisoning. Animal studies have shown, that, at least experimentally, it can produce its toxin also when inoculated intramuscularly. To our knowledge, however, a serious infection with this organism has never been reported in man. In fact, the bacillus has been found in human wounds in only three cases, all reported by Hall[1] in 1945.

In Hall's cases, only one patient had any untoward symptoms. He suffered incipient gas gangrene with a temperature of 105 F., and induration with crepitus of his injured leg. Sulfonamide therapy and surgery were utilized with a final satisfactory result. The two patients without symptoms harbored Cl. botulinum type A. The first patient's organism was type B.

Studies on the intramuscular injection of Cl. botulinum into animals have shown that it is not difficult to produce fatal infections. The symptoms in animals inoculated by extra-oral routes are reported to be identical with the classical symptoms of botulism following toxin ingestion.

It is of interest to note how few spores may produce an infection when the tissue is necrosed by formaldehyde solution. In 1929 Coleman conducted such a study in guinea pigs and found that 25 heated spores could cause a fatal infection.[2] The symptoms occurred in three to four days, with death two to eight hours later.

When calcium chloride is injected with Cl. botulinum spores, infection is also facilitated, as shown by Edmonson, Giltner and Thom[3] in 1920. When the chloride and spores were in the same area the incubation period was short; when they were injected 3 to 4 cm. apart the incubation period was sometimes lengthened to two weeks.

Botulinum may spread from the original site through the blood stream as indicated by Orr,[4] 1922, who found that the bacillus could frequently be recovered from the spleen when it was examined several days after an intramuscular injection.

Most of the workers doing experimental studies have found great differences in pathogenicity among various strains of the organism, and varying susceptibility in individual animals.

REPORT OF CASE

On Nov. 6, 1943, a 15 year old white girl was admitted to the Philadelphia General Hospital Fracture Service 20 min. after she had fallen from her second-story bedroom to the

---

Dr. Mattman is now Assistant Professor of Bacteriology, College of Liberal Arts, Wayne University, Detroit.

ground, landing on her feet. Both legs were splinted before she was moved to the hospital.

Physical examination revealed a superficial abrasion on the right lateral chest wall. The pulmonary status was normal. There was medial angulation of the left lower leg in the middle third. There was mobility and crepitus at this point, but no break in the skin. There was a 5 cm. jagged, open wound involving the lateral half of the right ankle through which the lateral malleolus protruded. This was caked with dirt and sand. The tibio-astragalar joint was dislocated medially and was filled with street filth. Circulation in the foot appeared to be normal, and a dorsalis pedis was palpable when the foot was rotated to approximate normal position. Sensation was normal in both legs and feet. Reflexes were not elicited in the lower extremities.

X-rays taken immediately on admission showed no evidence of fracture of the lumbar spine or the sacrum. There was a fracture of the left tibia and fibula in the midportion of the shaft, with lateral displacement of the fragments. There was a fracture of the medial malleolus and dislocation of the right ankle joint.

At operation, the exposed distal end of the right lateral malleolus was cleansed at length with copious amounts of warm saline and aqueous soap, and the wound enlarged longitudinally. The ligaments of the lateral side of the ankle joint were found to be ruptured, with the wound opening immediately into the joint space. When the joint had been cleansed completely, the ragged edges of the ligaments were excised and hemostasis obtained. Debridement was meticulous, and included all tissue which was not obviously viable and much viable tissue that could not be cleaned. Five grams of sulfanilamide crystals were placed in the wound. The skin, subcutaneous tissues, and lateral ligamentous structures were loosely approximated with four through-and-through interrupted black silk sutures. A rubber dam drain was placed behind the joint space, anterior to the Achilles tendon and brought out through a stab wound on the medial side to provide through-and-through drainage. Tissue was taken for culture.

Immobilization in approximate anatomical position was maintained by lateral molded plaster splints extending to the knee. The fractured left tibia was reduced by manual traction and immobilized with lateral molded plaster splints extending from the toes to the upper third of the thigh with the knee slightly flexed.

Postoperative x-ray study showed the left leg in nearly anatomical position. The position of the right ankle was satisfactory. When the patient was admitted to the ward after operation, her temperature was 98.8 F. (axillary), pulse 128, respiration 32.

Tetanus antitoxin in full prophylactic dose was given. The combined gas gangrene and tetanus antitoxin was not available. The patient was immediately started on sulfathiazole, later changed to sulfadiazine.[5]

Pain in the foot was noted at 8:30 a. m. of the first postoperative day, but investigation revealed no cause. Both legs were elevated. The temperature remained 99 to 99.8 F., with the pulse 80 to 100 per minute, respirations 30 to 40 per minute.

At 8:00 a. m. on the second postoperative day the temperature reached 101 F. The pulse was 90 and respirations 25. By evening the temperature was recorded at 101 F., pulse 130 per minute, respirations 30 per minute. The patient complained of pain in both feet, and it was noted that the right foot was cool.

Gas was discovered in the tissues on the third postoperative day (Nov. 9, 1943) extending to within 4 in. (10 cm.) from the knee. On that day radical incision of the leg, with slashes extending through the deep fascia from knee to dorsum of the foot, revealed normal tissue at the upper portion with good blood supply, but much necrosis and no free hemorrhage in the lower portion. The odor was typical of gas gangrene. Cultures were taken.

The leg was packed in ice and elevated. Polyvalent gas gangrene antitoxin, whole blood, plasma, and glucose were given. Extreme toxicity continued, and a guillotine type amputation was done through viable tissue just below the knee on the fifth day after injury.

The patient withstood surgery well, but did not show marked improvement after it although the previous treatment was continued.

X-ray examination of the left leg Nov. 16, 1943, ten days after injury, revealed a large amount of gas about the fracture site, extending almost to the head of the fibula laterally. Examination revealed crepitus over the middle third of the lower leg. The foot was pale but somewhat pink. A dorsalis pedis was not palpable.

On the same day, this leg was incised radically in a manner identical with the first procedure on the other leg. When this was done 150 cc. of foul pus was liberated with a gush, together with much gas and a distinct mousy odor. The family would not consent to amputation. X-ray therapy was given.

The patient gradually grew worse. On Nov. 20, (14 days after injury) she presented a striking picture of cyanosis, dysphagia, inability to speak and generalized muscular flaccidity. The mental processes seemed relatively unimpaired but diplopia and paresis of the extra-ocular muscles were apparent.

After this she became rapidly worse, and was pronounced dead 16 days after injury on Nov. 22. She had received intravenously a total of 55,000 units of perfringens mixed antitoxin in divided doses. She also had received five blood transfusions, each of 500 cc. of citrated whole blood. A lumbar sympathetic block with a 1% solution of procaine was repeated every 12 hr., following the original discovery of circulatory difficulties in the left leg. Intravenous fluids were administered in amounts sufficient to maintain urinary output in excess of 1,000 cc. daily. Sulfathiazole and later sulfadiazine were given in full dosage. Oxygen, opiates and sedatives were used as needed.

Cultural Studies.—The culture taken from the original wound showed beta hemolytic streptococci, a diphtheroid, alpha hemolytic streptococci, Clostridium tetanus, and an anaerobic gram-positive sporulating bacillus which was identified by mouse protection tests as Clostridium botulinum type A.[6]

Twelve mice were inoculated with the Seitz filtrate of a culture of this anaerobic rod. Two mice were left unprotected and the rest were divided into pairs and received one of the following types of antiserums: Cl. sordellii; Cl. botulinum type A; Cl. botulinum type B; Cl. tetani; Cl. novyi. Only the mice receiving Cl. botulinum type A antiserum survived. The other mice succumbed within 24 hr., exhibiting no symptoms except extreme weakness. This experiment was repeated with the same results. Cultural studies on the organism were also compatible with its identification as Cl. botulinum.

In the preliminary examination of the culture, separation of the Cl. botulinum from Cl. tetanus was accomplished by use of 6% agar in blood agar plates. It will be noted that the patient had received tetanus antiserum.

Autopsy Report.—Postoperative status: amputation of the right leg below the knee; wide incisions on the left leg below the knee. Comminuted fracture of the left tibia and fibula. Thrombosis of the left external iliac vein. Atelectasis, bronchopneumonia of the dependent portion of the lower lobes of both lungs with probable pulmonary embolism. Kidneys, swollen and congested. Liver, congested. Brain, acute and chronic passive congestion with hypoplasia of the circle of Willis.

A culture taken at autopsy from the wound of the leg which became secondarily involved, showed a beta hemolytic Streptococcus, and an alpha hemolytic Streptococcus, but no clostridia were isolated.

In 1929, Coleman[2] noticed in animal studies that occasionally growth of Cl. botulinum occurs in a very restricted area of involved muscle and that unless this particular area is examined no organisms may be found. Failure to isolate the organism in this instance cannot be regarded as proof of its absence at autopsy.

COMMENT

The nature of the original wound, and, in the early stages, the clinical course of this case were identical with typical cases of gas gangrene infection. The failure to respond to the wide incision and the subsequent amputation of the leg in which the compound fracture occurred must be assumed to have resulted from a blood-borne contamination and subsequent infection of the hematoma about the simple fracture of the opposite (left) tibia.

---

[5] Penicillin was not available at this date for general use.

[6] Serum for this examination was supplied by Dr. Ivan C. Hall.

The length of time which elapsed before death is striking, but most remarkable was the sudden alteration of the patient's appearance 14 days after injury, two days before death. (A two-week incubation period for parenteral botulism has been noted in animals.) Dysphagia and inability to speak resembled a pseudobulbar palsy. There was cyanosis, a generalized muscular flaccidity most apparent in paresis of the ocular muscles, and impaired respiratory effort followed by cyanosis. Up to this time and for a while thereafter the patient had been fairly alert mentally. The first subjective manifestation of the terminal phase was diplopia and inability to swallow even her own saliva.

The possibility of Cl. botulinum infection was not considered before the death of the patient, but in retrospect, the departures from the usual clinical course of the patient dying of gas gangrene mentioned above are striking in their resemblance to the described clinical course of botulism. None of those concerned with the care of this patient, however, had ever seen a case of food poisoning caused by botulism in a human being.

It cannot be stated definitely that this was a case of botulism from a wound infection. It is a case in which the patient died of gas gangrene of uncertain etiology. Perhaps, when more data on botulinum infections in human beings have been accumulated, it may be judged with more accuracy, or it may give a clue to problem cases of gas infection.

If serious botulinum wound infections do occur in man, a problem arises regarding diagnosis. The prolonged incubation of a culture necessary to demonstrate botulinum toxin, and the time which it frequently requires to obtain such an anaerobe in pure culture, makes cultural methods valueless for aid in possible therapy.

The findings of Coleman and Meyer,[7] 1922, might prove of interest in diagnosis. They inoculated serum of rabbits suffering from botulism into mice, with death of the mice resulting.

Active immunization to botulinum toxins has been accomplished in man by Reames and his associates.[8]

It might be of interest to include an examination of Cl. botulinum strains in the determination of the spectrum of antibiotics.

SUMMARY AND CONCLUSION

A fatal wound infection is reported in which Clostridium botulinum type A was isolated.

A striking similarity to the clinical course of botulism is noted in the terminal phases of this case.

The possibilities of human wound infection with Cl. botulinum is discussed, and the difficulties of early diagnosis are emphasized.

Recommendation for treatment must await further experience and studies.

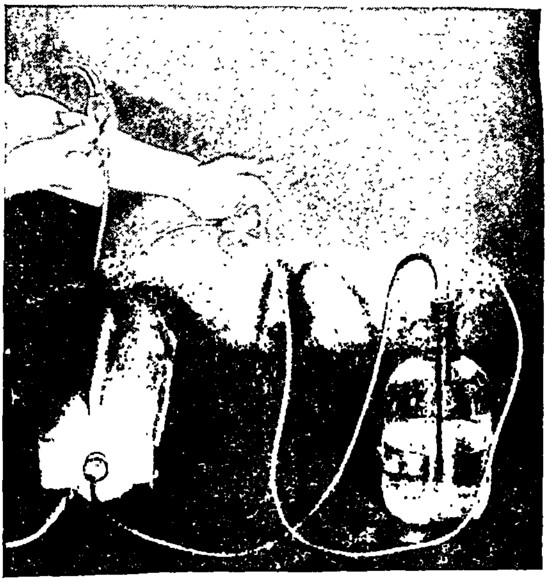
AEROSOL THERAPY

VACUUM CLEANER AS A PRACTICAL SOURCE OF POSITIVE PRESSURE FOR NEBULIZATION

John M. Sheldon, M.D.
Robert G. Lovell, M.D.
and
Kenneth P. Mathews, M.D., Ann Arbor, Mich.

Since aerosol inhalation therapy was advocated by Barach, Segal, Abramson and others[1] for the treatment of pulmonary edema, bronchial asthma, chronic bronchitis and certain suppurative lung conditions, penicillin by aerosol inhalation, in addition to its parenteral injection, has been employed when antibiotics are indicated. Bronchial dilators and sympathomimetic amines also now are given by aerosol. Because the duration of aerosol treatment is long, and the treatment may be prescribed for weeks or months, the practical problem arises as to how such therapy can be carried out at home.



DeVilbiss no. 40 nebulizer attached through "Y" tube to water filter jug and tank-type vacuum cleaner.

Efforts to provide a continuous stream of air pressure were made first by supplying a nebulizer with a rubber

tube, which, in turn, was attached to a bicycle pump. This required another person to pump the nebulizer while the patient inhaled the medication. In the next attempt the inner tube from a bus or truck tire was inflated, and when it was connected to the nebulizer by a rubber tube continuous pressure for nebulization was supplied for a short time. But the inner tube had to be reinflated prior to each treatment. Patients living near a large city were fortunate in that they could rent tanks of oxygen. By attaching the nebulizer to a hose leading from the tank, a satisfactory stream of pressure was provided. But this method is expensive and inconvenient.

We undertook to find a simple means of providing a source of positive pressure in the home. The vacuum cleaner, an article usually available, was discovered to be an effective mechanism for delivering continuous pressure for aerosol treatment. A few individual types of vacuum cleaner were found to exert insufficient pressure for this purpose. However, any model which will power a paint sprayer attachment works well, since the nebulizer operates on the same principle.

Results of Experiment: Summary of Data

Type of Nebulizer	Source of Pressure	No. of Nebulizers Used	L. per Min. Flow	Medication Used	Average Amount Medication Delivered in 2 Min. (Gm.)	Remarks About Spray

The actual apparatus (fig.) is set up by obtaining a one-hole cork or rubber stopper and placing it on the attachment tube connected to the exhaust of the vacuum cleaner. Models which have no tube may be converted by putting a cork directly into the exhaust outlet. A 6 inch (15 cm.) piece of glass tubing, ranging from 5 to 8 mm. in diameter is placed through the cork and is attached to a 3 foot (91 cm.) length of rubber tubing. This is connected to a 10 inch (25 cm.) length of glass tube which goes through a two-hole rubber stopper placed in a gallon jug. The jug should be filled with enough water to cover the outlet of the glass tube leading from the vacuum cleaner. This cleans the air from the vacuum apparatus and prevents blowing dust into the nebulizer. Through the other hole in the two-hole rubber stopper in the jug, a short piece of glass tubing is run, to which is attached about 5 feet (1.5 meters) of rubber tubing. This is interrupted about 12 inches (30 cm.) from the end by a glass Y tube. The Y tube allows for escape of air when the patient is exhaling and when it is not necessary to blow air through the nebulizer. This cuts down on waste of medication and provides for the maximum delivery of a given dose when the patient inhales. Coordination between the inspiratory effort and the patient's finger which covers the Y tube when he inhales is easily managed but should be supervised by the doctor before he lets his charge begin a course of regular treatment by aerosol. A nebulizer which is attached to the end of the rubber tube may vary greatly in its ability to perform.[1e] A type which we have found most satisfactory and which is reasonable in price is the DeVilbiss no. 40 apparatus. The nebulizer should be filled with 1 or 2 cc. of medication at a time, and care should be taken to see that the patient holds the nebulizer so that the opening does not direct toward the base of the tongue, but rather directly toward the posterior pharynx. If the patient tips it too far backward or upward, a great amount of medication is lost on the mucous membranes of the mouth. All stoppers should be removed from the nebulizer before aerosolization is started.

EXPERIMENT

Three types of nebulizer were used, and at least four of each model were employed. Sources of pressure were as follows: compressed air at 7½ pounds (3.4 Kg.); oxygen from a tank, flowing at 8 liters per minute, and pressure from two different types of vacuum cleaner. One was an upright tank type (vacuum cleaner 1), and the other was a horizontal tank type (vacuum cleaner 2). Medications used were as follows: distilled water; 1:200 isopropylepinephrine mixed in a propylene glycol base with small amounts of procaine, atropine and an ephedrine-like compound[2] included; and aqueous penicillin with 20,000 units per cubic centimeter. These were chosen since they were a representative group of the characteristic types of medication given by aerosol. It was felt that if the rather oily mixture of "aerolin" were well aerosolized, and the aqueous solutions also were well dispensed, most other medications likewise would do well in the apparatus. Exactly 2 cc. of the liquids was placed singly into the nebulizers, and each was weighed. They were then attached one after another to the pressure source being studied, which in turn was attached to the jug and tubing. Pressure was applied for exactly two minutes in most cases. If the 2 cc. of material was completely dispensed before two minutes had elapsed, the time was recorded. The nebulizers then were reweighed and measured in grams. A flow meter was placed at the end of the system where the nebulizer had been and pressure applied, both with and without the nebulizer in place. Flow in liters per minute with the nebulizer in place was recorded.

---

[2] Eli Lilly & Company, Inc., Aerolin compound, solution no. 50.

RESULTS

It was found that the amount of medication delivered by the vacuum cleaner apparatus was not so great as that released in an equal time when air pressure or oxygen was used. However, a clinically acceptable stream of mist was delivered by the nebulizers when attached to the vacuum cleaner apparatus. The aerosol material released by oxygen or air pressure was about four times as great as that yielded from vacuum cleaner pressure. This, however, is not discouraging because aerosolization by oxygen pressure usually is not conducted at 8 liters per minute, but more likely at between 4 and 6 liters per minute. Furthermore, a considerable quantity of the material nebulized by air or oxygen is wasted no matter how it is dispensed.

SUMMARY

The prolonged use of nebulized medication has necessitated the development of some way in which aerosolization can be carried on in the patient's home. It has been shown that a nebulizer will dispense, by aerosol, medicaments such as penicillin and various sympathomimetic amines when attached to most modern models of vacuum cleaner in the manner outlined.

ADDENDUM

The continued use of penicillin by inhalation over a long period of time may result in sore throat or irritation if given in too strong a concentration. We have found that penicillin when given by aerosol should be made from crystalline penicillin and should be administered in concentration usually no greater than 20,000 units per cubic centimeter. As a rule patients tolerate this strength of medication well.

Role of Drugs in Plant Economy.—Another important field for future research, and one as yet almost unexplored, is the study of the way in which drugs are formed in plants and the function they fulfil in the economy of the plants in which they are found. It is a remarkable fact that, for almost every one of the numerous vegetable drugs in use today, there is no convincing explanation of their presence in the plant. The importance of quinine to the cinchona tree or of morphine to the poppy, for example, are complete mysteries. It is possible that some of the poisonous or obnoxious substances are a form of protection against grazing animals or the ravages of destructive insects and other pests. It is possible, too, that some drugs result from the combination of waste products formed in the vital processes of the plant, and represent a method of inactivating substances which might otherwise be harmful. Yet such explanations have little to commend them except plausibility; the factual evidence is scanty indeed. Information on these points is valuable, not only for its own sake, but also because any added understanding of the metabolic processes of plants may prove of great importance in solving outstanding agricultural problems.—T. I. Williams, D. Phil., Drugs from Plants, London, Sigma Books Limited, 1947.

COUNCIL ON PHYSICAL MEDICINE AND REHABILITATION

The Council on Physical Medicine and Rehabilitation has authorized publication of the following reports.

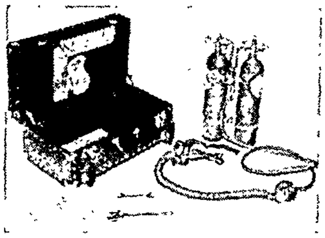
Howard A. Carter, *Secretary.*

SCOTT DEMAND INHALATORS ACCEPTED

Manufacturer: Scott Aviation Corporation, 207 Erie Street, Lancaster, N. Y.

The Scott Demand Inhalators, Models A and B, are portable devices with face masks for controlling the administration of oxygen to patients from tanks of the compressed gas. As they are ordinarily applied, with the mask over the patient's face, the oxygen flows at any rate "demanded" by the patient, and (in the words of the manufacturer) "there is no interference with, nor any tendency to influence, the natural respiratory cycle." If greater assistance seems necessary, the pressing of a button starts a continuous flow of oxygen at slight positive pressure. If the supply of oxygen is depleted, a safety valve opens automatically and substitutes air for oxygen.

Model A is the lighter form of the apparatus, consisting essentially of the gauge assembly, the regulator proper, the connecting tube, and the mask. It weighs 2.6 kg. (5¾ lb.); for shipment it makes a package measuring 16 by 20 by 51 cm. (6 by 8 by 20 in.) and weighing 3.6 kg. (8 lb.). The foreign shipping weight (with wood shipping case) is 8.1 kg. (18 lb.).



Scott Demand Inhalator

Model B, with carrying case, is the heavier form. It measures 20 by 30.5 by 56 cm. (8 by 12 by 22 in.), and weighs 13 kg. (28¾ lb.). For shipment it makes a package measuring 35.6 by 25.4 by 61 cm. (14 by 10 by 24 in.) and weighing 22 kg. (48 lb.). The foreign shipping weight is 30 kg. (66 lb.). Motive power is simply that of the compressed gas and the patient's own respiratory movements.

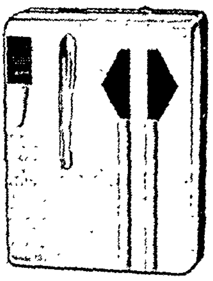
Evidence of satisfactory construction was obtained from sources acceptable to the Council. It was emphasized that the devices are effective with patients whose spontaneous breathing is sufficiently fast and deep, and in addition is useful as an adjunct to manual artificial respiration, but is not adequate (and is not intended) for use in patients whose breathing is very slow or very shallow. The Council on Physical Medicine and Rehabilitation voted to include the Scott Demand Inhalators, Models A and B, in its list of accepted devices.

AUDICON HEARING AIDS ACCEPTED

Manufacturer: National Earphone Co., Inc., 20 Shipman Street, Newark 2, N. J.

The Audicon Hearing Aids, Models 400 and 415, are electrical instruments of conventional design and construction. Excluding clips, switches, etc., they measure 73 by 57 by 20 mm. With batteries they weigh 124 gm. Without batteries, cord or receiver they weigh 76 gm.

Evidence of satisfactory construction and performance was obtained from sources acceptable to the Council. The Council on Physical Medicine and Rehabilitation voted to include the Audicon Hearing Aids, Models 400 and 415, in its list of accepted devices.



Audicon Hearing Aid

REPORT OF THE COUNCIL

The Council on Physical Medicine and Rehabilitation has authorized publication of the following report.

The Council wishes to express its appreciation for the valuable cooperation of the Advisory Committee on Audiometers and Hearing Aids for its expert services. The Committee members are Drs. Gordon Berry, Richard K. Cook, Hallowell Davis, Kenneth M. Day, Edmund P. Fowler, Isaac H. Jones, Dean M. Lierle, M. H. Lurie, Douglas Macfarlan, and C. Stewart Nash.

HOWARD A. CARTER, *Secretary.*

HEARING AIDS AND ADVERTISING

The modern hearing aid is a triumph of electronic and acoustical engineering and Yankee ingenuity. Manufacturers of hearing aids are to be congratulated on their success. Electronically the modern hearing aid is essentially a small public address system except for size and weight. A hearing aid with batteries weighs as little as 5 to 10 oz., whereas a public address system may weigh as much as 25 to 50 lb. Many of the component parts of all makes of hearing aids are obtained from the same suppliers. One hearing aid manufacturer makes some of its vacuum tubes but in general the manufacturers buy them from one source. One manufacturer uses an electromagnetic microphone but most of the microphones are of the crystal type. The resistors, capacitors and other circuit components come from several sources and are similar to products used in other electronic instruments and devices. The outside case which houses the chassis is distinctive for each manufacturer and there are usually differences in the circuits that are employed. The modern electrical hearing aid is truly a significant achievement when one realizes that it has been less than 75 years since Bell invented the telephone.

Although the statistics are not clear, probably three million persons in the United States are sufficiently hard-of-hearing to need either hearing aids or lip reading or both. On the other hand, probably only 800,000 to one million hard-of-hearing individuals are willing to wear a hearing aid. The other two million are potential customers for hearing aids, and the manufacturers vie with one another to obtain their patronage. It also appears that these two million, if the estimate is correct, are not much interested in acquiring hearing aids. They probably have several reasons for not getting one. Three of these reasons are: 1. A sense of pride and a desire to conceal their hearing handicap. 2. They have a hearing defect which is not materially assisted by a hearing aid. 3. The first cost is too great.

It has not been many years since deafness and impairment of hearing occasioned ridicule and derisive laughter. The use of the old-fashioned trumpet provoked amusement, and some regarded the condition as a prelude to imbecility or senility. Therefore, it is little wonder that manufacturers of hearing aids today, bent on marketing their wares, make use of advertising with claims, sometimes implicit, often explicit, that "nothing shows," that "one's hearing is hidden," and that nothing is carried around that will reveal a handicapping hearing loss.

In the opinion of the Advisory Committee on Audiometers and Hearing Aids, this attitude is not a healthy one and can only lead to false hopes on the part of the prospective hearing aid wearer and to disappointment and bitterness which further handicap the hard-of-hearing person.

Advertising is for the purpose of announcing to the world that a manufacturer or dealer has a product or service to sell. In the words of the late Dr. Glenn Frank, "Advertising is the spark plug of industry." Advertising is also an educational medium. When advertising is used in its most ethical and commendable manner, it is an excellent educational medium. Thus publicity and propaganda can be used for good. But they can be used for evil too. The hearing aid industry is a highly competitive field and the method employed by most manufacturers to market hearing aids is through a dealer. The industry is dependent on the number of leads of prospective purchasers who can be reached. There seems to be a certain combination of credulity and optimism in the hard-of-hearing person, and, when alluring claims are made about secrecy and invisibility, these hard-of-hearing persons, eager to hear again and to satisfy their vanity, will answer but will be disappointed on learning of the deception. Even if the salesman is fortunate enough to sell an instrument, the hard-of-hearing individual will feel that he has been ensnared and misled.

During the last year or two, the Council has noted such phraseology as the following in advertising for various hearing aids:

"a fabulous new electronic ear which miraculously conceals deafness"; "no button in the ear"; "hide your deafness"; "you can hear better, farther and more clearly"; "the world's smallest hearing aid"; "the new invisible hearing aid"; "a new hearing aid is small, powerful and invisible"; "a revolutionary type of hearing aid"; "no batteries, no wires, it really is invisible"; "new miracle electronic ear hides deafness"; "let me show you how you can hear invisibly"; "you understand everything you hear"; "world's finest, smartest and smallest hearing aid"; "hear in secret."

The Council on Physical Medicine and Rehabilitation and its Advisory Committee on Audiometers and Hearing Aids must regard such clichés as misleading and unwarranted. The alleged concealment may amount only to the substitution of a flesh-colored tube for a wire.

The Council realizes that if manufacturers are to prosper in business they must sell hearing aids and encourage those who need hearing aids to buy them. However, the Council feels that misleading methods of persuading people to buy will not help but will have a tendency to pull down the level of integrity of the industry, and will strengthen the resistance that already exists in the minds of many hard-of-hearing individuals against buying the instruments.

The Council on Physical Medicine and Rehabilitation and its Advisory Committee on Audiometers and Hearing Aids believe that a great deal of misleading advertising and undesirable promotional activity can be remedied by a strong trade organization of the hearing aid manufacturers. Such an organization does exist, but it is new and is having its growing pains. Several years ago, Fair Trade Practices Codes for the Hearing Aid Industry were promulgated by the Federal Trade Commission. The general principles laid down in the codes would probably eliminate all or most of the advertising abuses if the manufacturers and dealers would pay more attention to them. The National Better Business Bureau is now working on a set of standards in cooperation with the American Hearing Aid Association.

The development of the truly effective hearing aids of the present day proved to be the most powerful factor in bringing about the virtual disappearance of quack devices from the market. In the same way it is to be hoped that the development of a more rational attitude on the part of the public toward hearing aids may bring about the disappearance of dishonest advertising. When people come to regard hearing aids as they now regard spectacles, there will be even less excuse than there is now for promotion by misrepresentation, and a hard-of-hearing person denied a hearing aid will complain as vehemently as would a myopic person denied spectacles. Some of the advertising in the past has made the hard-of-hearing person undeniably a victim and a dupe; a campaign of informative, educational advertising can put him in his rightful place as an intelligent person promptly availing himself of the latest products of modern electroacoustic laboratories.

The Council and its Advisory Committee will from time to time publish articles to call attention to misleading and unwarranted advertising of hearing aids. It will also continue its policy of recognizing well-made, ethically promoted hearing aids by publishing a list of instruments found acceptable.

which in turn was attached to the jug and tubing. Pressure was applied for exactly two minutes in most cases. If the 2 cc. of material was completely dispensed before two minutes had elapsed, the time was recorded. The nebulizers then were reweighed and measured in grams. A flow meter was placed at the end of the system where the nebulizer had been and pressure applied, both with and without the nebulizer in place. Flow in liters per minute with the nebulizer in place was recorded.

RESULTS

It was found that the amount of medication delivered by the vacuum cleaner apparatus was not so great as that released in an equal time when air pressure or oxygen was used. However, a clinically acceptable stream of mist was delivered by the nebulizers when attached to the vacuum cleaner apparatus. The aerosol material released by oxygen or air pressure was about four times as great as that yielded from vacuum cleaner pressure. This, however, is not discouraging because aerosolization by oxygen pressure usually is not conducted at 8 liters per minute, but more likely at between 4 and 6 liters per minute. Furthermore, a considerable quantity of the material nebulized by air or oxygen is wasted no matter how it is dispensed.

SUMMARY

The prolonged use of nebulized medication has necessitated the development of some way in which aerosolization can be carried on in the patient's home. It has been shown that a nebulizer will dispense, by aerosol, medicaments such as penicillin and various sympathomimetic amines when attached to most modern models of vacuum cleaner in the manner outlined.

ADDENDUM

The continued use of penicillin by inhalation over a long period of time may result in sore throat or irritation if given in too strong a concentration. We have found that penicillin when given by aerosol should be made from crystalline penicillin and should be administered in concentration usually no greater than 20,000 units per cubic centimeter. As a rule patients tolerate this strength of medication well.

Role of Drugs in Plant Economy.—Another important field for future research, and one as yet almost unexplored, is the study of the way in which drugs are formed in plants and the function they fulfil in the economy of the plants in which they are found. It is a remarkable fact that, for almost every one of the numerous vegetable drugs in use today, there is no convincing explanation of their presence in the plant. The importance of quinine to the cinchona tree or of morphine to the poppy, for example, are complete mysteries. It is possible that some of the poisonous or obnoxious substances are a form of protection against grazing animals or the ravages of destructive insects and other pests. It is possible, too, that some drugs result from the combination of waste products formed in the vital processes of the plant, and represent a method of inactivating substances which might otherwise be harmful. Yet such explanations have little to commend them except plausibility; the factual evidence is scanty indeed. Information on these points is valuable, not only for its own sake, but also because any added understanding of the metabolic processes of plants may prove of great importance in solving outstanding agricultural problems.—T. I. Williams, D. Phil., Drugs from Plants, London, Sigma Books Limited, 1947.

COUNCIL ON PHYSICAL MEDICINE AND REHABILITATION

The Council on Physical Medicine and Rehabilitation has authorized publication of the following reports.

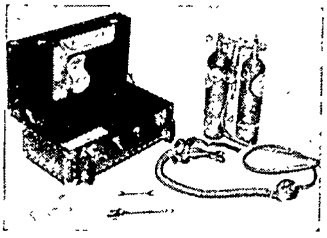
HOWARD A. CARTER, *Secretary.*

SCOTT DEMAND INHALATORS ACCEPTED

Manufacturer: Scott Aviation Corporation, 207 Erie Street, Lancaster, N. Y.

The Scott Demand Inhalators, Models A and B, are portable devices with face masks for controlling the administration of oxygen to patients from tanks of the compressed gas. As they are ordinarily applied, with the mask over the patient's face, the oxygen flows at any rate "demanded" by the patient, and (in the words of the manufacturer) "there is no interference with, nor any tendency to influence, the natural respiratory cycle." If greater assistance seems necessary, the pressing of a button starts a continuous flow of oxygen at slight positive pressure. If the supply of oxygen is depleted, a safety valve opens automatically and substitutes air for oxygen.

Model A is the lighter form of the apparatus, consisting essentially of the gauge assembly, the regulator proper, the connecting tube, and the mask. It weighs 2.6 kg. (5¾ lb.); for shipment it makes a package measuring 16 by 20 by 51 cm. (6 by 8 by 20 in.) and weighing 3.6 kg. (8 lb.). The foreign shipping weight (with wood shipping case) is 8.1 kg. (18 lb.).



Scott Demand Inhalator

Model B, with carrying case, is the heavier form. It measures 20 by 30.5 by 56 cm. (8 by 12 by 22 in.), and weighs 13 kg. (28¾ lb.). For shipment it makes a package measuring 35.6 by 25.4 by 61 cm. (14 by 10 by 24 in.) and weighing 22 kg. (48 lb.). The foreign shipping weight is 30 kg. (66 lb.). Motive power is simply that of the compressed gas and the patient's own respiratory movements.

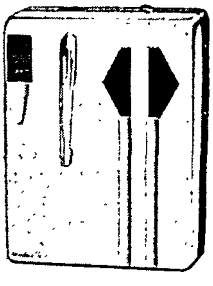
Evidence of satisfactory construction was obtained from sources acceptable to the Council. It was emphasized that the devices are effective with patients whose spontaneous breathing is sufficiently fast and deep, and in addition is useful as an adjunct to manual artificial respiration, but is not adequate (and is not intended) for use in patients whose breathing is very slow or very shallow. The Council on Physical Medicine and Rehabilitation voted to include the Scott Demand Inhalators, Models A and B, in its list of accepted devices.

AUDICON HEARING AIDS ACCEPTED

Manufacturer: National Earphone Co., Inc., 20 Shipman Street, Newark 2, N. J.

The Audicon Hearing Aids, Models 400 and 415, are electrical instruments of conventional design and construction. Excluding clips, switches, etc., they measure 73 by 57 by 20 mm. With batteries they weigh 124 gm. Without batteries, cord or receiver they weigh 76 gm.

Evidence of satisfactory construction and performance was obtained from sources acceptable to the Council. The Council on Physical Medicine and Rehabilitation voted to include the Audicon Hearing Aids, Models 400 and 415, in its list of accepted devices.



Audicon Hearing Aid

REPORT OF THE COUNCIL

The Council on Physical Medicine and Rehabilitation has authorized publication of the following report.

The Council wishes to express its appreciation for the valuable cooperation of the Advisory Committee on Audiometers and Hearing Aids for its expert services. The Committee members are Drs. Gordon Berry, Richard K. Cook, Hallowell Davis, Kenneth M. Day, Edmund P. Fowler, Isaac H. Jones, Dean M. Lierle, M. H. Lurie, Douglas Macfarlan, and C. Stewart Nash.

Howard A. Carter, *Secretary.*

HEARING AIDS AND ADVERTISING

The modern hearing aid is a triumph of electronic and acoustical engineering and Yankee ingenuity. Manufacturers of hearing aids are to be congratulated on their success. Electronically the modern hearing aid is essentially a small public address system except for size and weight. A hearing aid with batteries weighs as little as 5 to 10 oz., whereas a public address system may weigh as much as 25 to 50 lb. Many of the component parts of all makes of hearing aids are obtained from the same suppliers. One hearing aid manufacturer makes some of its vacuum tubes but in general the manufacturers buy them from one source. One manufacturer uses an electromagnetic microphone but most of the microphones are of the crystal type. The resistors, capacitors and other circuit components come from several sources and are similar to products used in other electronic instruments and devices. The outside case which houses the chassis is distinctive for each manufacturer and there are usually differences in the circuits that are employed. The modern electrical hearing aid is truly a significant achievement when one realizes that it has been less than 75 years since Bell invented the telephone.

Although the statistics are not clear, probably three million persons in the United States are sufficiently hard-of-hearing to need either hearing aids or lip reading or both. On the other hand, probably only 800,000 to one million hard-of-hearing individuals are willing to wear a hearing aid. The other two million are potential customers for hearing aids, and the manufacturers vie with one another to obtain their patronage. It also appears that these two million, if the estimate is correct, are not much interested in acquiring hearing aids. They probably have several reasons for not getting one. Three of these reasons are: 1. A sense of pride and a desire to conceal their hearing handicap. 2. They have a hearing defect which is not materially assisted by a hearing aid. 3. The first cost is too great.

It has not been many years since deafness and impairment of hearing occasioned ridicule and derisive laughter. The use of the old-fashioned trumpet provoked amusement, and some regarded the condition as a prelude to imbecility or senility. Therefore, it is little wonder that manufacturers of hearing aids today, bent on marketing their wares, make use of advertising with claims, sometimes implicit, often explicit, that "nothing shows," that "one's hearing is hidden," and that nothing is carried around that will reveal a handicapping hearing loss.

In the opinion of the Advisory Committee on Audiometers and Hearing Aids, this attitude is not a healthy one and can only lead to false hopes on the part of the prospective hearing aid wearer and to disappointment and bitterness which further handicap the hard-of-hearing person.

Advertising is for the purpose of announcing to the world that a manufacturer or dealer has a product or service to sell. In the words of the late Dr. Glenn Frank, "Advertising is the spark plug of industry." Advertising is also an educational medium. When advertising is used in its most ethical and commendable manner, it is an excellent educational medium. Thus publicity and propaganda can be used for good. But they can be used for evil too. The hearing aid industry is a highly competitive field and the method employed by most manufacturers to market hearing aids is through a dealer. The industry is dependent on the number of leads of prospective purchasers who can be reached. There seems to be a certain combination of credulity and optimism in the hard-of-hearing person, and, when alluring claims are made about secrecy and invisibility, these hard-of-hearing persons, eager to hear again and to satisfy their vanity, will answer but will be disappointed on learning of the deception. Even if the salesman is fortunate enough to sell an instrument, the hard-of-hearing individual will feel that he has been ensnared and misled.

During the last year or two, the Council has noted such phraseology as the following in advertising for various hearing aids:

"a fabulous new electronic ear which miraculously conceals deafness"; "no button in the ear"; "hide your deafness"; "you can hear better, farther and more clearly"; "the world's smallest hearing aid"; "the new invisible hearing aid"; "a new hearing aid is small, powerful and invisible"; "a revolutionary type of hearing aid"; "no batteries, no wires, it really is invisible"; "new miracle electronic ear hides deafness"; "let me show you how you can hear invisibly"; "you understand everything you hear"; "world's finest, smartest and smallest hearing aid"; "hear in secret."

The Council on Physical Medicine and Rehabilitation and its Advisory Committee on Audiometers and Hearing Aids must regard such clichés as misleading and unwarranted. The alleged concealment may amount only to the substitution of a flesh-colored tube for a wire.

The Council realizes that if manufacturers are to prosper in business they must sell hearing aids and encourage those who need hearing aids to buy them. However, the Council feels that misleading methods of persuading people to buy will not help but will have a tendency to pull down the level of integrity of the industry, and will strengthen the resistance that already exists in the minds of many hard-of-hearing individuals against buying the instruments.

The Council on Physical Medicine and Rehabilitation and its Advisory Committee on Audiometers and Hearing Aids believe that a great deal of misleading advertising and undesirable promotional activity can be remedied by a strong trade organization of the hearing aid manufacturers. Such an organization does exist, but it is new and is having its growing pains. Several years ago, Fair Trade Practices Codes for the Hearing Aid Industry were promulgated by the Federal Trade Commission. The general principles laid down in the codes would probably eliminate all or most of the advertising abuses if the manufacturers and dealers would pay more attention to them. The National Better Business Bureau is now working on a set of standards in cooperation with the American Hearing Aid Association.

The development of the truly effective hearing aids of the present day proved to be the most powerful factor in bringing about the virtual disappearance of quack devices from the market. In the same way it is to be hoped that the development of a more rational attitude on the part of the public toward hearing aids may bring about the disappearance of dishonest advertising. When people come to regard hearing aids as they now regard spectacles, there will be even less excuse than there is now for promotion by misrepresentation, and a hard-of-hearing person denied a hearing aid will complain as vehemently as would a myopic person denied spectacles. Some of the advertising in the past has made the hard-of-hearing person undeniably a victim and a dupe; a campaign of informative, educational advertising can put him in his rightful place as an intelligent person promptly availing himself of the latest products of modern electroacoustic laboratories.

The Council and its Advisory Committee will from time to time publish articles to call attention to misleading and unwarranted advertising of hearing aids. It will also continue its policy of recognizing well-made, ethically promoted hearing aids by publishing a list of instruments found acceptable.

PREVENTION OF CHRONIC DISEASE

The recent National Conference on Preventive Aspects of Chronic Disease,[1] convened by the Commission on Chronic Illness, demonstrated remarkable enthusiasm on the part of many national agencies and persons representing different professional fields, for working together on what has been aptly termed the common denominator aspects of chronic illness. Prevention, including the detection of asymptomatic chronic disease, is one such common denominator, because many chronic diseases have common causative factors or common causative settings, such as genetic factors, nutritional disturbances, emotional and environmental stress, and occupational causes. The conference represented a concentrated, concerted effort to explore avenues for more effective application of what is already known regarding the prevention of the major chronic diseases through control of known etiologic factors and through treatment of the earliest identifiable stages of these diseases. The final reports of the 12 working committees of the conference have now been prepared and sent to the conference participants. The commission has announced that a summary and a complete transcription of the conference proceedings and reports will be published.

A review of these reports reveals much thoughtful comment and many recommendations which deserve careful attention. In view of the current controversy over "screening," particularly "multiple screening," as a detection technique, the reports of two committees of the conference—on evaluation of detection and on detection in private practice—may be singled out as examples of the conference deliberations.

The Committee on Evaluation of Detection begins its report by defining screening tests as "procedures which sort out those who probably have abnormalities from those who probably do not." A complete periodic physical examination for every person is considered impracticable because of its expense and the limited number of physicians; therefore, rapid, inexpensive screening measures are needed. Their primary purpose is to bring persons with disease to physicians at an earlier stage than would otherwise be true. Although many such tests are now available, there is urgent need for their evaluation, with respect to the following criteria: 1. Reliability: How consistent are the results obtained by different techniques, at different times and under ordinary "field" conditions? 2. Validity: How often is the test right as determined by some final diagnostic process? 3. Yield: How many previously known and how many unknown cases are discovered by the tests? 4. Cost: What is the cost per test or per case found, in money and professional time? 5. Acceptance: How acceptable is the procedure to the public, the profession and to community agencies? The report stresses the need for insuring follow-up by physicians on presumptive "positives" but warns against unduly increasing the case-load on physicians through too extensive a screening program. The committee emphasizes the importance of evaluating emotional and psychological concomitants of the screening procedure and urges further study of this subject. Other points considered in need of special investigation are (1) how often screening tests should be repeated, (2) the effects of multiple screening projects on single screening programs, and (3) the practical limits of validity required for each disease and screening test, taking into account the prevalence and incidence of the disease, the expense of carrying out definitive diagnostic procedures and the psychological hazards involved, for example, in falsely indicating the possible presence of cancer.

The Committee on Detection in Private Practice distinguishes between detection and screening by terming the latter the "presumptive," rather than the definitive, "identification of ordinarily unrecognized disease." Important chronic diseases which can be detected at an early or "latent" stage are certain forms of cancer, certain forms of heart disease, (congenital, rheumatic, syphilitic), hypertension, malnutrition, obesity, visual defects, glaucoma, hearing defects, epilepsy, syphilis, diabetes, and pulmonary tuberculosis. The committee warns that detection of latent disease may have undesirable psychological effects if not carefully handled to insure that the patient does not exaggerate or misinterpret its significance. The committee's chief recommendation is that all physicians carry out detection in their own offices by utilizing the following procedures: (1) history, (2) physical examination, and (3) laboratory tests. However, recognizing the serious practical limitations to this recommendation, the committee suggests that mass screening tests be made available to physicians, as a service to which they may refer their patients. The committee listed 16 procedures or tests that could be incorporated into such a program.

These reports call attention to the fact that screening and detection, with some notable exceptions (such as chest x-ray on hospital admission), have been advocated largely with reference to the nonpatient population, and thus out of the normal physician-patient relationship. Although all "positive" cases are referred for final diagnosis to a physician, this attempt to establish a patient-physician relationship often fails. In view of the probably much higher "yield" of detection procedures when applied to persons who are already seeking medical care, Levin [2] has suggested that greater effort and attention be expended on this type of detection, which may be termed "*clinical detection*,"[2] in addition to the nonclinical variety. While the value of case-finding among persons who are not under medical care is not questioned, it is probable that greater concentration for this purpose on persons who seek medical care would yield greater dividends in the prevention and control of chronic disease.

THE BARUCH COMMITTEE ACHIEVES ITS GOALS

The announcement, on May 26, that the Baruch Committee on Physical Medicine and Rehabilitation had attained its objectives and was discontinuing its activities offered a magnificent example of the manner in which a voluntary effort toward the advancement of an important phase of medical practice can still be achieved in a free country by a willing group of workers. In this instance, the generosity of one person, Mr. Bernard M. Baruch, and the efforts of a group of medical scientists were responsible for extensive developments in the treatment of disease by physical agents and in the rehabilitation of disabled persons. The members of the Baruch Committee include Dr. John F. Fulton, Yale University; Dr. Charles G. Heyd, Columbia University; Dr. Andrew C. Ivy, University of Illinois; Dr. Frank H. Krusen, University of Minnesota (chairman); Dr. Chauncey D. Leake, University of Texas; Dr. Frank R. Ober, Harvard University; Dr. Winfred Overholser, St. Elizabeths Hospital, Washington, D. C.; Dr. Howard A. Rusk, New York University; Dr. Alfred R. Shands Jr., Alfred I. duPont Hospital for Crippled Children, Wilmington, Del.; Dr. Francis O. Schmitt, Massachusetts Institute of Technology; Dr. William S. Tillett, New York University, and Dr. Arthur L. Watkins, Harvard University. It is gratifying to note that Mr. Baruch's support of this new branch of medical practice will continue and that he has stated it will be his object to make further grants "to those who undertake the work with enthusiasm and beneficial results."

The activities of the Baruch Committee have been largely instrumental in bringing about (1) a marked increase in the teaching of physical medicine and rehabilitation in the medical schools of America, (2) an extensive increase in the number of residencies in physical medicine and rehabilitation, (3) advances in the rehabilitation of many thousands of wounded soldiers and sailors as well as still greater numbers of persons injured in civilian life, (4) recognition of the medical specialty of physical medicine and rehabilitation, (5) establishment of a new Section on Physical Medicine and Rehabilitation in the American Medical Association, (6) organization of an American Board of Physical Medicine and Rehabilitation to certify qualified specialists in the field, (7) stimulation of the establishment of community rehabilitation centers throughout the country, (8) clarification of the standards for determination of physical fitness of the workers of the nation, and (9) improvements in the teaching of medical physics.

One of the leading medical educators in this country commented: "Certainly I do not think that, in this country, any similar effort in medicine has achieved so great a degree of success in so short a period of time." Dr. Frank H. Krusen, chairman of the committee, assuredly was justified in stating, when he thanked his associates, "Mr. Baruch's generosity and your labors have been humanitarian contributions of tremendous magnitude toward the welfare of our democracy."

The success of this project is of especial significance at this particular time, when various leaders of medicine, education, statesmanship, and industry are embarking on a similar private enterprise in aid to medical education by establishing the National Fund for Medical Education. The successful completion of the work of the Baruch Committee presents definite proof of the fact that it is still possible to obtain significant advances in medical practice, teaching, and research in the voluntary American way. If the generosity of one philanthropist and the efforts of a relatively small group of medical scientists can accomplish so much, all who are interested in the free practice of medicine should look with assurance to the new National Fund for Medical Education, which has already received the generous financial support of many persons. Through the active efforts of medical scientists and others, it can achieve unlimited success.

POSTPARTUM NECROSIS OF THE PITUITARY

Simmonds[1] in 1914 described a man with clinical symptoms suggestive of hypopituitarism and postmortem lesions the essential feature of which was the destruction of the pituitary. The syndrome represented a condition of insufficiency of the anterior lobe of the pituitary. Conditions capable of causing necrosis of the pituitary consist of tumors, cysts, gumma, massive tuberculous necrosis, granulomas of unknown etiology, hypophysectomy and healed postpartum necrosis of the anterior lobe of the pituitary.

Sheehan[2] described massive focal atrophy of the anterior pituitary, which occurs only in women and is nearly always of postpartum origin. The lesion is an ischemic necrosis similar in type to an infarct and occupying most of the anterior lobe. Sheehan reported 13 cases of fresh pituitary necrosis and one of healed pituitary necrosis observed in the course of two years at the Glasgow Royal Maternity and Women's Hospital. The necrosis was found in patients who died at any time from 14 hours post partum onward. Hemorrhage and collapse at delivery were present in all of his cases. According to Sheehan, the anterior pituitary hypertrophies normally during pregnancy to two or three times its normal size. The gland involutes rapidly during the puerperium. Presumably there is a sudden reduction of the blood flow to the gland at about the time of delivery, owing to severe hemorrhage. If, in addition, there is a severe general circulatory collapse, the blood flow to the anterior pituitary may for a short time be reduced almost to nothing. This may cause thrombosis in the sinuses of the gland, which in turn may lead to necrosis of the tissue.

[2] Sheehan, H. L.: Post-Partum Necrosis of the Anterior Pituitary, Edinburgh M. J. 45 tr.: 13 (March) 1938

Escamilla and Lisser[3] collected from the literature 595 cases with "more or less suggestive" evidence of Simmonds' disease. The diagnosis was established both clinically and pathologically in 101. The occurrence of loss of weight, amenorrhea and a low basal metabolic rate in a woman whose symptoms date from postpartum hemorrhage and collapse warrants, in their opinion, a clinical diagnosis of Simmonds' disease. They emphasize the frequent confusion of Simmonds' disease with anorexia nervosa. The latter usually occurs in young girls in the absence of a history of pregnancy. The condition not infrequently clears up with proper psychiatric and nutritional therapy.

Sheehan[4] in 1949 reported on autopsies in 95 cases culled from the literature and considered by him as definite examples of chronic severe hypopituitarism. These cases presented severe chronic fibroid lesions of the anterior pituitary, intracellular cysts and tumors and surgical hypophysectomies. The clinical symptoms and pathological lesions in these cases were compared with the various findings in 70 cases of clinical postpartum necrosis of the pituitary. Severe deficiency of the pituitary function is manifested clinically, according to Sheehan, by a syndrome made up of the following characteristics: in many cases a history of severe circulatory collapse as result of hemorrhage and shock at a delivery; atrophy of the gonads and genital tract with complete amenorrhea; impotence and loss of libido; complete loss of pubic and axillary hair; absence of normal skin pigment; a typical flabby facies with thinning of the eyebrows and pallor; increased sensitivity to cold; weakness; mental torpidity with slow speech; a low basal metabolic rate; very low urinary excretion of 17-ketosteroids; insulin sensitivity and hypoglycemia unresponsiveness, and a tendency to spontaneous hypoglycemia and coma. Sheehan stresses that patients with hypopituitarism face the grave danger of a particular type of coma which is often fatal.

Cook and co-workers,[5] in a recent publication, reported on seven cases of postpartum necrosis of the anterior pituitary observed at the university hospitals of the State University of Iowa during the period of 1935 to 1950. The diagnosis in four was verified by autopsy. A history of collapse from severe hemorrhage during the last delivery was obtained in six. In five of the six cases with adequate history there was amenorrhea with complete loss of sexual function and libido. These authors point out that, while anorexia may develop, it is not an important symptom and is never as extreme as in anorexia nervosa. They also stress the observation made previously by Sheehan, that cachexia and emaciation are not commonly seen in Simmonds' disease.

The treatment of anterior pituitary necrosis has thus far been disappointing. A replacement of the hormonal secretions with anterior pituitary extracts has not been efficacious. Knowlton[6] reports only "minimal changes" in a patient with long-standing hypopituitarism who was given corticotrophin (ACTH) during 10 days. Cook and his co-workers report good response in one patient from small doses of cortisone supplemented by high sodium chloride dietetic intake and thyroid medication. The role of both corticotrophin and cortisone in the treatment of pituitary insufficiency has not yet been determined. The best treatment so far seems to be prophylaxis, with better recognition and correction of the complications of pregnancy that lead to collapse during delivery.

NONTOXIC INFLUENZA VACCINE

McKee,[1] of the University of Iowa department of bacteriology, reports the production of a nontoxic variant of influenza A virus, with immunizing properties superior to those of routine toxic influenza A virus. The virus used in this study was originally isolated from the 1943 outbreak in Iowa City and had been passed repeatedly in chick embryos but had never been in mice. Two methods of subculture were adopted. By the first method, 0.5 cc. of freshly harvested undiluted allantoic fluid (hemagglutination titer 1:6,400) was inoculated into the allantoic sac of a 11 day old chick embryo. By the second method similar inoculation was made with a 1:10,000 dilution of the same fluid. All inoculums contained 500 units per cubic centimeter of pencillin and streptomycin.

After 24 to 48 hours of incubation at 37 C., the hemagglutination titer was the same (1:6,400) in both series. The two series, however, differed widely in mouse toxicity. After the use of the dilute inoculum, the virus retained its original pathogenicity, almost invariably killing mice in two to three days followng intranasal injection, with autopsy showing almost complete pulmonary consolidation. After use of the undiluted inoculum, the virus was nonpathogenic, few if any symptoms being shown on intranasal inoculation in mice, whose lungs almost invariably were free from demonstrable lesions.

Used as primary vaccines in mice, the two viruses stimulate the production of almost identical antibody titers. As booster vaccines, however, the nontoxic variant is twice as effective as the toxic culture. In a typical experiment, the antibody level (hemagglutination-inhibition) rose to 5,120 units after a toxic booster inoculation and to 10,240 units after a nontoxic inoculation.

Clinical tests were made on 200 student volunteers. Each was given 1 cc. of formalized virus subcutaneously. Two weeks later, the antibody titer had risen to an average of 3,667 units after the toxic injection and to 5,216 units after the nontoxic injection. Twenty per cent of the

100 students given the toxic vaccine had reactions such as general malaise, muscular aches, headache, or fever. Of the 100 students given the nontoxic virus, only 5% experienced similar discomforts. Marked reduction in the toxicity of the influenza virus following large inoculums into chick embryos was previously reported by Kempf and Harkness [2] of the University of Illinois.

MEETING OF THE SUBCOMMITTEE ON STEROIDS AND CANCER

The recently concluded two-day meeting of the Subcommittee on Steroids and Cancer at American Medical Association Headquarters demonstrated that the collaborative study sponsored by the Subcommittee has evolved into an efficient reliable method for evaluating cancer therapy. Criteria for selecting cases of mammary cancer to be treated with the hormones, recommendations for optimum dosage schedules, and delineation of the advantages and shortcomings of this form of therapy have evolved as a result of the study, which was begun four years ago. The Subcommittee on Steroids and Cancer is a subcommittee of the Committee on Research of the Council on Pharmacy and Chemistry. At this year's sessions, 64 assembled oncologists initially heard an analysis of the pooled results of their reports to the Committee on Research and then engaged in panel discussion of the mechanism of action of the steroid hormones in mammary cancer. On the second day, the influence of the steroid hormones on neoplasms of the genitourinary tract and bone and newer developments in cancer research and therapy were discussed.

Review of the proceedings indicates that the role of the androgens and estrogens in the treatment of mammary carcinoma has been thoroughly assessed; therefore, widening of the scope of investigation to seek new cancer-inhibiting agents and new fields of application of the hormones seems desirable. Equivocal results were reported in hormone therapy of cancer of the cervix, endometrium, and ovary. More extensive study and analysis of pooled results are required before an opinion can be formed of the value of this therapy.

In addition to the sex steroids, cortisone and corticotrophin (ACTH) were tested in terminal cases of various types of neoplasia. These agents allay pain and induce a feeling of well-being but do not alter the course of the disease. In several cases, despite the subjective response and improved appearance of the patient, there was evidence of more rapid spread of the neoplasm and autopsy later even revealed that the spleen was riddled with metastases.

Tracer studies with radioactive estrogen in mammary cancer showed higher concentration of radioactivity in the involved breast tissue than in random samples from other tissues. Attempts at total pituitary inhibition by irradiation were unsuccessful as evidenced by 17-ketosteroid excretion, the corticotrophin and epinephrine tests, radioactive iodine up-take, basal metabolic rate, and gonadotropic assay. In another series, similarly treated, amenorrhea developed in several patients.

Total adrenalectomy was advocated to control increased adrenal androgen excretion in patients with prostatic cancer who had had prior orchectomy and estrogenic therapy. This may be a feasible procedure, since adequate adrenocortical substitution therapy is now available. The resultant cessation of androgen excretion may permit a longer period of control of the lesion.

Of diagnostic and prognostic importance was a report concerning variation in blood serum levels of the two antiproteases (antichymotrypsin and antirennin) in normal subjects and in cancer patients. Normal values range up to 5 West units for antichymotrypsin and above 5 units for antirennin. In cancer patients, these values tend to reverse, the antirennin titer dropping below, and the antichymotrypsin titer rising above, 5 units. The patient's response to therapy may be judged by rise in antirennin and fall in antichymotrypsin titer. These investigations of enzyme systems are merely preliminary and require tests in other chronic diseases, but they may disclose something of the nature of fundamental cancer-inhibiting mechanisms.

The investigators and the subcommittee are to be commended for their zeal and enthusiasm in pursuing these studies. They have not only established a pattern for future investigations of fundamental medical problems but also have demonstrated the ability of physicians to carry on a voluntary, cooperative, scientific research project during peacetime.

A complete transcript of the proceedings of the Second Spring Conference on Steroid Hormones and Mammary Cancer will be published in a limited edition for distribution to the investigators and other interested persons.

CONTRIBUTIONS TO FOUNDATION DEDUCTIBLE

At the time the American Medical Education Foundation was established, application was made to the Commissioner of Internal Revenue requesting that he declare the Foundation exempt from federal income tax, on the basis that it is a corporation organized and operated exclusively for educational purposes. This application has now been acted upon, and the Commissioner has ruled that the Foundation is exempt from federal income tax under Provision 101 (6) of the Internal Revenue Code for the year 1951. This ruling means that contributions received by the Foundation in 1951 are deductible by the donors in computing their taxable net income in the manner and to the extent provided by Section 23 (o) and (q) of the Code.

This prompt ruling by the Commissioner should stimulate further support of the Foundation, since contributors are now assured that their contributions are deductible. Physicians desiring to make a donation to the Foundation will find a convenient contribution form included in the Foundation's announcement on pages 28 and 29 in the advertising section of this issue of THE JOURNAL.

ORGANIZATION SECTION

THE WORLD MEDICAL ASSOCIATION—MEETING OF THE COUNCIL IN GENEVA

The Council of The World Medical Association held its mid-year session at Geneva, Switzerland, April 29 to May 6, 1951. The council, which is the governing body of the association between sessions of the General Assembly, meets twice a year. There are 12 nations represented in the membership of the council.

One of the most important events of the meeting was a two-day conference between officials of The World Medical Association and officials of the World Health Organization. This conference consisted of an informal exchange of views on important problems of mutual interest.

The topics covered by the discussions included the possibility of holding an international conference on questions of professional and technical education. It was agreed that tentative plans for such a conference would be submitted to the governing bodies of WHO and WMA. The purpose of the conference, which will be held in either 1952 or 1953, would be to stimulate the improvement of standards of training for medical and related personnel. This is a problem which both WHO and WMA consider essential in view of the urgent needs of underdeveloped regions for larger numbers of health personnel.

Other topics discussed included (1) measures to promote the free flow of essential medical supplies between countries and the difficulties caused by shortages resulting from the present world situation; (2) assistance to be given to WHO by The World Medical Association in the selection of suitable experts for work in various fields; (3) exchange of information and documentation on subjects of common interest, and contributions by each organization to publications of the other; (4) cooperation of The World Medical Association in assuring the widest possible adoption of international non-proprietary names recommended by WHO for drugs and pharmaceutical products with due recognition of recommendations of the discoverers of the products; (5) assistance of WHO, through its various publications, in making known the "International Code of Medical Ethics" adopted by The World Medical Association, and (6) representation of The World Medical Association in regional conferences of WHO.

The medical associations of Western Germany and Japan were elected to membership in The World Medical Association after a canvas had been made of the opinions of all member associations. It was brought out clearly that both applicants had gone on record as decrying war crimes and accepting the principles enunciated in the Declaration of Geneva as applying to all their members, present and future.

The Japan Medical Association adopted the following resolution March 30, 1949:

> "That the Japan Medical Association, representing the doctors of Japan, takes this occasion to denounce atrocities perpetuated on the enemy during the war period, and to condemn acts of maltreatment of patients which are alleged and in some cases known to have occurred.
>
> A. Takahashi, M.D.,
> President,
> The Japan Medical Association"

The Western Germany Medical Association adopted the following statement on Jan. 28, 1950:

"The German medical profession had to acknowledge with indignation and with deep regret the participation, during the time of the Third Reich, of certain German doctors, both individually and collectively, in numerous acts of cruelty and oppression, and in the organization and perpetration of brutal experiments on human beings without their consent. We acknowledge that, in performing these acts and experiments, which have resulted in the deaths of millions of human beings, the German medical profession has violated the ethical tradition of Medicine, has debased the honor of the medical profession, and has prostituted medical science in the service of war and political hatred. The convicted criminals have been punished, some by Allied, others by German Courts.

"We express our regret that the system of dictatorship rendered impossible insight into these occurrences and has strangled every expression of free opinion. We hereby declare that we abhor and reject the crimes perpetrated since 1933 in Germany and in other countries by members of our profession.

"In making this statement to the WMA we solemnly promise the medical profession and the whole world that we will do all we can to prevent in the future such a betrayal of medicine through German doctors. We hereby repeat our resolution adopted on October 18, 1947, on our initiative and published thereafter and refer to the reports issued by the "Arbeitsgemeinschaft Westdeutscher Aerztekammern" concerning the Nuremburg trials against 20 SS doctors, scientists and three high officials and to our position expressed in this publication. The German medical organization will do its best to prosecute medical men who shall be found guilty of offenses against their professional duties by professional jurisdiction. We shall act in the same manner against doctors who are not willing to promise a high standard of professional behavior in the future.

"Accordingly, the '52 Deutsche Aerztetag' in altering its professional regulations has required every doctor to subscribe to the Declaration of Geneva adopted by the W.M.A. in Geneva in 1948."

This statement was signed by Drs. Neuffer, Borck, Rodewald, Rieder, Stockhausen, Weiler and Weise, for the Arbeigsgemeinschaft der Westdeutschen Arztekammern.

Under the provisions of Article 6 II of the Constitution and Article 7 of the By-Laws, the Bulgarian Medical Association was announced as dropped from membership in The World Medical Association.

The number of national associations now members of The World Medical Association is 41. Applications were received or were announced as forthcoming from five other associations.

Reports were received from the assistant secretaries for Asia, Europe and Latin America as to conditions in their respective areas.

An extended discussion took place on social security as it affects medical practice and a progress report from the committee on that subject was accepted.

The Committee on Medical Education presented an important report and, following lengthy discussion, the Council voted to find ways and means of calling a World Conference on Medical Education in 1953. Other international organizations will be asked to participate. The tentative agenda for the conference will cover the following points: (*a*) What is the aim of undergraduate medical education? (*b*) What should be the requirements for entrance into medical school? (*c*) What should be the general character of the curriculum after entrance?

In discussion of these points, many details will be considered. The place of the conference will be somewhere in Europe.

The Council decided to study further the subject of medical certification to see what, if anything, can be done to simplify and standardize such certificates.

The council studied in detail the proposal to establish an International Centre for the Study of Medical Jurisprudence. This proposal envisages that such a center would recommend, encourage and undertake studies of comparative medical jurisprudence, and draw conclusions from such studies and draft proposals concerning medical jurisprudence in both peace and war.

While the Council has no objections to the establishment of such a center for purposes of collecting and distributing information, it feels very definitely that such a center composed as it would be of those qualified to speak for only a small portion of the medical profession, would greatly exceed its prerogatives if it endeavored to lay down regulations governing the medical profession in peace and war.

The World Medical Association has already established an International Code of Medical Ethics. It is qualified to speak for well over 500,000 physicians and it has in its membership the national medical associations of 41 countries. If the Code requires any elaboration to cover a war-time situation, the organizations most qualified to discuss the matter are The World Medical Association, the World Health Organization, the International Committee of the Red Cross, and the League of Red Cross Societies, and certainly not the organizations concerned in establishing this proposed center. A resolution was drafted setting forth the opinion of the Council and is to be sent to all member associations and other organizations having any real or fancied interest in the subject.

Means of cooperation with the International Committee of the Red Cross, the League of Red Cross Societies, and the International Council of Nurses, as well as with the World Health Organization, were elaborated. Numerous matters of routine business were transacted and committee reports on miscellaneous subjects were discussed.

Because of the illness of the chairman, Dr. T. C. Routley of Canada, the meetings were presided over by the vice chairman, Dr. Pierre Glorieux of Belgium.

The social events in connection with the meeting were as follows: a reception tendered by the officials of the city of Geneva, a dinner by the Geneva Medical Society, a reception and dinner at Berne by the Federation des Medecins Suisses, receptions by the International Committee of the Red Cross, the League of Red Cross Societies, and receptions by various individuals resident in Geneva.

REGISTRATION UNDER THE HARRISON NARCOTIC ACT

Physicians who are registered under the Harrison Narcotic Act or under the Marihuana Tax Act must effect reregistration on or before July 1 to avoid a penalty. Each year, despite the annual warnings in THE JOURNAL, this requirement is overlooked by some physicians, and unpleasant consequences follow. Failure to register adds a penalty of 25% to the tax payable and, in addition, subjects the physician to the possibility of a fine not exceeding $2,000 or to imprisonment for a maximum of five years, or to both. The commissioner of internal revenue has in past years given some tardy registrants the choice of paying sums by way of compromise, a procedure authorized by law, or accepting criminal prosecution. If this procedure does not produce the required promptness in reregistration, the commissioner will have no choice but to institute criminal prosecution.

DR. ALBRIGHT RECEIVES GOLDBERGER AWARD

Dr. Fuller Albright, associate professor of medicine at Harvard Medical School, Boston, received the Joseph Goldberger Award in clinical nutrition for his continuing studies in the field, on June 13 during the Harvard Medical Alumni Association dinner in Atlantic City. The award, a gold medal and $1,000, named after the late Dr. Joseph Goldberger, who did pioneer work on pellagra in the southern states, was established to honor physicians who have made important contributions to the knowledge of nutrition and is made periodically by the American Medical Association to stimulate research in the field.

MEDICAL LEGISLATION

STATE

Alabama

Bills Introduced.—H. 239, proposes regulations for the sterilization of mentally inferior, mentally deficient or feeble minded inmates in the Partlow State School for Mental Deficients. H. 308, proposes regulations providing a state scholarship program to promote the education of nurses. H. 315, proposes to provide a state scholarship program to promote the education of Negro nurses. H. 316, proposes an appropriation to provide facilities for a nurses' educational program in certain tuberculosis sanatoriums of the state.

California

Bills Enacted.—A. 1504 has become Chapter 580 of the Laws of 1951. It amends the Welfare and Institutions Code by adding regulations relating to epileptics, among which are provisions making it possible to commit such persons to state hospitals when they are in need of treatment or when they are suffering from mental illness in addition to epilepsy. S. 129 has become Chapter 540 of the Laws of 1951. It authorizes the State Department of Public Health to Prescribe and promulgate minimum standards of safety and sanitation in the physical plant, and of diagnostic, therapeutic and laboratory facilities for public medical institutions and to certify to the State Department of Social Welfare those institutions which meet the standards established.

Connecticut

Bill Introduced.—H. 1705, proposes to broaden the scope of the Connecticut Medical Service Plans so as to include certain types of dental surgery.

Bill Enacted.—H. 549, has become Public Act No. 49. It amends the narcotic act by defining the word "opiate" as including all synthetic drugs having addiction-forming or addiction-sustaining properties similar to morphine and so proclaimed by the president of the United States under the provisions of the federal narcotic law.

Florida

Bills Introduced.—H. 926, proposed the enactment of a child molester act, which would provide, among other things, for the psychiatric examination by two licensed psychiatrists of persons convicted under the act. Such psychiatrists should have had at least five-year exclusive practice in the diagnosis and treatment of mental disorders. H. 1062, proposes the creation of a special hospital district for Volusia County, Florida. H. 1332, proposes to authorize certain judges and county solicitors throughout the State to secure the services of a physician in connection with the investigation of crime or under circumstances where such services are deemed necessary for the investigation of crime. It also proposes to fix the fee to be paid to such physicians for the services which they render. H. 1385, proposes to authorize the Board of County Commissioners of Saint Lucie County to enter into contracts to provide and secure insurance on the employees of the county and the members of their family, which insurance shall provide funds to defray medical, surgical, hospital, and other similar expenses for such persons. H. 1440, proposes the creation of a special hospital district for Broward County, Florida. S. 876, proposes to authorize the City of Miami Beach, Fla., to establish a health plan for officers and employees of the city and their families.

Bill Enacted.—H. 150 became law without approval, May 22, 1951. It provides that any doctor or other practitioner of any of the healing sciences making a physical or mental examination of any person shall, upon request of such person, his guardian, curator or personal representative in the event of his death, furnish copies of all reports made of such examination or treatment. Such reports would not be furnished, however, except upon the written authorization of the patient, to any person other than his guardian, curator or personal representative.

Maine

Bill Enacted.—H. 869 was approved May 21, 1951. It provides an appropriation for the purpose of supplying materials in connection with the accumulation, storage and maintenance of 5,000 units of liquid plasma and 500 units of dried plasma to be available in the event of a disaster.

New Jersey

Bill Enacted.—A. J. R. 14 has become Joint Resolution No. 8 of the Laws of 1951. It creates a commission to examine and make a study of the laws dealing with the sale, dispensation, and distribution of narcotics.

Texas

Bill Enacted.—H. J. R. 38 was adopted May 17, 1951. It proposes an amendment to the Constitution providing for the establishment of a state medical education board and a state medical scholarship fund from which grants, loans, or scholarships may be made to students desiring to study medicine, provided such students shall agree to practice in rural areas of the state.

This summary was prepared by the Bureau of Legal Medicine and Legislation.

MEDICAL NEWS

CALIFORNIA

Medical Officer at San Quentin.—Dr. Morton D. Willcutts, Bethesda, Md., has been appointed chief medical officer for San Quentin Federal Prison to replace Dr. Leo L. Stanley, who recently retired after many years' service to the penitentiary. Dr. Willcutts, who retired from the navy after World War II with 34 years' active duty, began his new duties April 16.

Southern California Gastroenterologists.—The Southern California Society of Gastroenterology was organized in September, 1950, with subsequent meetings in November, January, and March. Drs. Albert M. Snell, Palo Alto; Donald C. Balfour, Rochester, Minn., and Walter L. Palmer, Chicago, have addressed the society. Meetings are scheduled on alternate months at the auditorium of the Los Angeles County Medical Association, 1925 Wilshire Blvd., Los Angeles. Present officers of the society are Dr. William C. Boeck, president; Dr. Grant Harold Lanphere, vice president, and Dr. Harold L. Thompson, secretary-treasurer, all of Los Angeles. Those interested in joining the society should make application to the Secretary, 2202 W. Third St., Los Angeles 5.

Dr. Legge Receives Knudsen Award.—Dr. Robert Thomas Legge, professor emeritus of hygiene and former university physician on the Berkeley campus of the University of California, has received the William S. Knudsen Award from the American Association of Industrial Physicians and Surgeons. The honor, given only eight times in 36 years, was presented to Dr. Legge during the association's 36th annual meeting in Atlantic City, N. J., in April. As university physician Dr. Legge organized a students' health service and inaugurated a system of medical records that has long been a model. In 1930 he planned the Ernest V. Cowell Memorial Hospital. As lecturer in industrial medicine at the university's medical school, he established courses in industrial health. Dr. Legge organized the section on industrial medicine of the California State Medical Association and was its first chairman. He was one of the organizers and first presidents of the Western Association of Industrial Physicians and Surgeons and was first president of the Pacific Section of the American College Health Association. For 11 years he has been associate editor of *Industrial Medicine and Surgery.*

CONNECTICUT

Alcohol Clinic.—A full-time outpatient service for diagnosis and treatment of alcoholism is in operation in Waterbury. Dr. Daniel O. Sayers is in charge of the clinic program and is assisted by a full-time mental hygienist, a consultant psychologist, and a secretary. It is anticipated that the clinic will become integrated in the total public health services of the community. Cooperation will be extended to all public and private agencies, to physicians, the clergy, personnel officers in industry, members of Alcoholics Anonymous, and to others who are called on to deal with the alcoholic.

Diabetes Detection Report.—More than 20,000 tests were conducted during the 1950 annual Diabetes Detection Drive sponsored by the Connecticut Diabetes Association in cooperation with the state medical society and the state department of health. The program produced more than 500 positive urine specimens, 251 of which concerned individuals not previously known to be diabetic. The number of tests represented an increase of 63 per cent over the 12,000 tests conducted in 1949. Private physicians conducted 2,917 tests; local health departments or testing stations, 10,534, and industrial medical departments, 2,095. The 1950 tests covered 1 per cent of the state population as compared to 0.6 per cent tested in 1949. Analysis of positive specimens by age groups indicates 12.1 per cent under 15 years, 13.7 per cent from 15 to 40 years, 19 per cent over 40 years, with age not stated in 55.2 per cent of the cases. Positives by sex disclose a higher percentage for women, 54.5 per cent, as compared to 45.5 per cent for men. The large increase in positive specimens among children under 15 years of age, from 2.5 per cent of the total positives in 1949 to 12.1 per cent in 1950, can be accounted for by the large number of school children tested in New Haven County during the 1950 drive.

ILLINOIS

Society Election.—The 1951-1952 officers of the Illinois Association of Medical Health Officers are: Drs. Leroy L. Fatherree, Joliet, president; Edward A. Piszcek, Chicago, vice president, and Herbert S. Ratner, Oak Park, secretary-treasurer. The association consists of full-time public health physicians.

Personal.—Kenneth J. Franklin, D.Sc., professor of physiology at the University of London, St. Bartholomew's Hospital Medical College, has been appointed visiting professor of physiology at the University of Illinois for the academic year beginning Sept. 1. His address will be: Department of Physiology, College of Natural Arts and Science, Urbana, Ill.

Medical Assistants of Quincy.—The Medical Secretaries and Assistants Club of Quincy, sponsored by the Adams County Medical Society and the Swanberg Medical Foundation of Quincy, was organized April 23. Its principal purpose is to promote educational programs adapted to the work of the members, to promote a closer relationship between members and their employers, and to further the relationship of the profession with the public and the patient. Membership is open to all women who have been employed by an Adams County physician, dentist, clinic, hospital, or health department. Those similarly employed in other counties of the Quincy territory may also join. Information may be obtained from the secretary, Miss Alice Rupert, 209-224 W. C. U. Building, Quincy.

Chicago

Audiology Grants-In-Aid.—The Audiology Foundation, to encourage and support adequate training of students, is offering again this year a limited number of grants-in-aid to students entering or already engaged in any branch of audiology, including otology, audiometry, speech, acoustics and education of the deaf or hard of hearing. These grants-in-aid will pay $500 per year and will be granted on the recommendation of professional teachers in audiology centers. For further information address the Audiology Foundation, 1104 S. Wabash Ave., Chicago 5.

Subsidiary Scholarships.—Four subsidiary scholarships of $10,000 each have been awarded to the Chicago Medical School this year by the David, Josephine and Winfield Baird Foundation, Inc., of New York. Another award of like amount has been given by Mrs. Sadye Arkin, Chicago, in memory of her husband, Harry J. Arkin. A subsidiary scholarship subsidizes the school for the difference between what a student pays in tuition and what the school must expend for his four years of training.

Research Group Receives Award.—The 1950 Commercial Solvents Award in antibiotics was presented to the terramycin research team of Charles Pfizer & Co., Inc., at the annual meeting of the Society of American Bacteriologists. The award consists of a gold medal and $1,000. The Pfizer group was selected for the discovery of the antibiotic, terramycin. The Commercial Solvents Award is administered by the Society of American Bacteriologists. It is awarded to any person or group of persons working in the Western Hemisphere who have contributed outstanding work in the field of antibiotics during the year.

University Appointments.—Dr. Herbert C. Batson, Washington, D. C., became professor of biostatistics at the University of Illinois College of Medicine on May 1. Dr. Batson will be concerned with work in biometrics and design of experiments.

Physicians are invited to send to this department items of news of general interest, for example, those relating to society activities, new hospitals, education and public health. Programs should be received at least three weeks before the date of meeting.

He taught bacteriology and immunology at South Dakota State College from 1932 to 1940 and was associated with the bureau of laboratories, Michigan Department of Health, from 1940 to 1946.

Dr. Percival Bailey has been appointed director of the Illinois Neuropsychiatric Institute in Chicago. He will continue to serve in his joint position as distinguished professor of neurology and neurological surgery at the University of Illinois College of Medicine and as research consultant for the Illinois state mental hospitals. Dr. Bailey will also advise and assist state mental hospitals and institutions of the state department of public welfare in developing and carrying out research programs. The Illinois Neuropsychiatric Institute is a research and educational facility that is operated and maintained by the state department of public welfare. The medical staff is provided by the University of Illinois College of Medicine.

INDIANA

University Committee.—In conformity with a resolution adopted by the general assembly, Gov. Henry F. Schricker has named a five-member committee to investigate the possibility of enlarging the Indiana University School of Medicine. Named as chairman was Dr. Merrill S. Davis, Marion, president of the medical school alumni organization; Mr. Virgil M. Simmons, Fort Wayne, publisher of the Fort Wayne *Journal Gazette;* Otto P. Kretzmann, D.D., Valparaiso, president of Valparaiso University; Mr. C. F. Eveleigh, Indianapolis, executive vice president of Eli Lilly & Co., and State Senator Leo J. Stemle, Jasper, an attorney. The committee will report to the 1953 session of the general assembly.

MASSACHUSETTS

Society Election.—At the recent meeting of the Massachusetts Trudeau Society held at the Worcester County Sanatorium, Worcester, Dr. Francis P. Dawson Jr., Waltham, was re-elected president; Dr. John W. Strieder, Brookline, was re-elected vice president, and Dr. David S. Sherman, Boston, was re-elected secretary-treasurer.

Course on Epilepsy.—A course in the diagnosis and treatment of epilepsy and in electroencephalography is to be conducted at the seizure division of the Children's Medical Center, Boston, under a special grant from the Children's Bureau acting through the Massachusetts Department of Public Health. A limited number of physicians and prospective electroencephalographic technicians will be accepted. The first course begins July 1. Details may be secured from state or territorial health departments, or from Dr. William G. Lennox, 300 Longwood Ave., Boston, who will have general direction of the course.

MICHIGAN

Michigan Memorial Research Program.—As a memorial to faculty and students who served during World War II, the University of Michigan has begun a research program in the development of peace-time use of atomic energy. Two years ago the university set up its Michigan Memorial-Phoenix Project and is now canvassing the alumni for funds for research. Means to alleviate malignant forms of high blood pressure without surgery will be sought in some of the 15 new investigations launched in May as a result of alumni gifts to the project. Expenditures for research thus far total $70,000. Many proposals are in the planning stage in anticipation of the 6½ million dollars the project contemplates spending within the next 10 years through various colleges of the university.

MINNESOTA

Probation for Abortionist.—On April 6 Helen A. Heck, 809 Iglehart Ave., St. Paul, was placed on probation by Judge Gustavus Loevinger in the District Court of Ramsey County. The probation is to cover a maximum period of eight years and follows a plea of guilty on Sept. 19, 1950, by the defendant to an information charging her with the crime of abortion and a prior conviction in 1947 for a similar offense. The defendant served six months in the Ramsey County jail prior to April 6 in connection with the present case. She has no license to practice any form of healing.

NEW JERSEY

Blood-Typing Program for College Women.—As a result of a blood-typing program carried on at New Jersey College for Women, Rutgers University, New Brunswick, seniors leaving the campus this month will carry identification cards stating their blood type and Rh factor. Forty-five girls from the advanced physiology and bacteriology classes at the college blood-typed more than 300 students and faculty members during May. The project, under the direction of Hazel B. Gillespie, Ph.D., associate professor of bacteriology, and Marion A. Reid, Ph.D., assistant professor of zoology, is part of the New Jersey College for Women civil defense program.

NEW YORK

Dr. Curphey Appointed Consultant.—Dr. Theodore J. Curphey, Garden City, chairman of the council committee of public health and education of the Medical Society of the State of New York, has been appointed a special consultant in clinical pathology to the Surgeon General of the U. S. Public Health Service. His post will be with the laboratory branch of the communicable disease center, Bureau of State Services.

Postgraduate Lecture.—On June 18 Dr. John L. Pool, assistant professor of clinical surgery at Cornell University Medical College, will deliver a postgraduate lecture for the Geneva Academy of Medicine in the Belhurst Restaurant, Geneva, at 8:30 p. m. on "Trends in Thoracic Surgery of Neoplastic Diseases." This lecture has been arranged by the Medical Society of the State of New York in cooperation with the New York State Department of Health.

Wadsworth Lecture.—The second Augustus B. Wadsworth lecture was given in Albany on May 16 by Dr. Francis G. Blake, Sterling professor of medicine, Yale University School of Medicine, New Haven, Conn., on antibiotic therapy with particular reference to chloramphenicol, aureomycin, and terramycin. The lectureship was established in 1950 by the staff of the division of laboratories and research of the New York State Department of Health and the council of the New York State Association of Public Health Laboratories. Dr. Wadsworth retired as director of the division of laboratories and research in 1945 after 31 years' continuous service.

Personals.—Dr. Temple Fay, professor of neurosurgery at the Woman's Medical College of Pennsylvania, has been appointed consultant to the Albany Hospital cerebral palsy treatment center.——Dr. Samuel W. Hamilton, Cedar Grove, N. J., addressed members of the Long Island Psychiatric Society and members of the Veterans Administration Hospital, Northport, L. I., May 15 on "The Ward Physician."——Mr. William Vogt, author of "Road to Survival" and former chief of the conservation section of the Pan-American Union, has been appointed national director of the Planned Parenthood Federation of America. He returned from Scandinavia in February on the completion of a population study made under combined Guggenheim and Fulbright fellowships.

New York City

Memorial to Doctor Bohrer.—A fully equipped and modern operating room has been installed in Knickerbocker Hospital as a memorial to the late Dr. John V. Bohrer, who was associated with the hospital for 15 years and was chief of the surgical service for six years prior to his death. Funds for the equipment of the new operating room were donated by physicians and surgeons now on the hospital's staff and by friends and associates.

Dr. Dubos Wins Trudeau Medal.—Rene J. Dubos, Ph.D., of New York, a member of the Rockefeller Institute for Medical Research, department of pathology and bacteriology, has received the Trudeau Medal of the National Tuberculosis Association. The award for "the most meritorious contribution on the cause, prevention, or treatment of tuberculosis" was presented by Dr. Esmond R. Long, director of medical research, in behalf of Dr. Florence R. Sabin, Denver, formerly with the Rockefeller Institute, who was chairman of the award committee. In the citation attention was called to Dr. Dubos' work in devising a method of culturing tubercle bacilli that promotes their growth throughout the medium, contrary to their habit of clumping together near the surface, and also speeds the growth of the germs. The great advantage of the technique, according to the citation, is to "open the long road to the study of the chemical nature of virulence in tubercle bacilli and broaden the foundation for the study of immunology of tuberculosis." A native of France, Dr. Dubos in 1927 became a fellow of the Rockefeller Institute. He is a member of the committee of medical research of the American Trudeau Society and vice president of the Society of American Bacteriologists.

Yeshiva University Medical Education Council.—An 11-man council of medical education has been formed to guide the development of the projected medical school at Yeshiva University. Dr. Harry M. Zimmerman, professor of pathology at Columbia University College of Physicians and Surgeons, has been elected chairman. Dr. Donald G. Anderson, Chicago, Secretary, American Medical Association's Council on Medical Education and Hospitals, and Dr. John B. Pastore, assistant professor of clinical obstetrics and gynecology at Cornell University Medical College, will serve as consultants. The projected medical center will contain schools of medicine, dentistry, nursing, public health, and postgraduate divisions. Members of the council include: Dr. Bernard J. Alpers, Philadelphia, professor of neurology at Jefferson Medical College; Dr. Leo Davidoff, clinical professor of neurosurgery at New York University College of Medicine; Dayton J. Edwards, Ph.D., professor emeritus of physiology at Cornell University Medical College; Dr. Harry H. Gordon, professor of pediatrics at the University of Colorado School of Medicine, Denver; Dr. Horace L. Hodes, clinical professor of pediatrics, Columbia University; Dr. Marcus Kogel, city commissioner of hospitals; Dr. Louis H. Nahum, professor of physiology at the Yale University School of Medicine, New Haven, Conn.; Dr. Isadore Snapper, director of medical education at Mt. Sinai Hospital; Dr. Abraham White, vice-president and director of research, Chemical Specialties Company, Inc.; Dr. Maxwell M. Wintrobe, professor of internal medicine at the University of Utah Medical School, Salt Lake City, and Dr. Harry M. Zimmerman, professor of pathology at Columbia University. In 1950 New York State's board of regents amended the charter of Yeshiva University, founded in 1897 as a theological seminary, empowering it to open a medical and dental school.

SOUTH DAKOTA

Dean Slaughter Named Consultant.—Dr. Donald H. Slaughter, dean of the University of South Dakota School of Medical Sciences, Vermillion, has been appointed consultant to the postgraduate Army Medical School in Washington, D. C. Dr. Slaughter lectured to students at the school in May and June on "The Philosophy of Medical History."

TENNESSEE

Visiting Professors.—Five visiting professors will join the faculty of the University of Tennessee Medical Units for the summer quarter beginning July 9. Frederic R. Steggerda, Ph.D., who served as an instructor in the division of physiology from 1929 to 1933, will return as a visiting professor of physiology. Dr. Steggerda is now a professor at the University of Illinois, Urbana. Four other professors joining the staff of the division of anatomy are: James H. Leathem, Ph.D., New Brunswick, N. J.; G. Gordon Robertson, Ph.D., Dallas, Texas; Robert L. Bacon, Ph.D., and Dr. Donald L. Stilwell, San Francisco.

TEXAS

Guest Lecturers Organization.—The department of radiology of the University of Texas Medical Branch, Galveston, under the direction of Dr. Joe C. Rude, has developed a guest lecturers organization. Dr. Walter J. Stork, Houston, is chairman; Dr. Carroll F. Crain, Alice, is vice chairman, and Dr. Rude is acting as temporary secretary. The organization includes 37 radiologists from Texas, Oklahoma, and Louisiana. The object of the group is to promote interest of Southwest physicians in radiology and to support the highest possible standards for radiological work in the Southwest.

UTAH

Personals.—At a recent meeting of the American Board of Anesthesiology Dr. Scott M. Smith of Salt Lake City was elected a director of the board.——Dr. George M. Fister, Ogden, was among the 17 distinguished University of Chicago alumni to be awarded a citation of merit at the alumni assembly in Chicago June 9.

State Board of Health.—Dr. James Z. Davis, Salt Lake City health commissioner, has succeeded Dr. Thomas J. Howells as chairman of the state board of health. Dr. Davis has served on the board for the past two years. The retiring chairman has been a member of the board for 18 years and has also served twice as acting state health commissioner.

WEST VIRGINIA

Lay Diabetes Society.—The first meeting of the new Kanawha Diabetic Lay Society was held at the YWCA in Charleston the middle of March. Throughout the state similar lay societies are being formed that will ultimately amalgamate with the West Virginia Diabetes Association.

Grants for Heart Research.—A grant of $3,000 for research in heart disease has been awarded the school of medicine at West Virginia University, Morgantown, by the board of directors of the West Virginia Heart Association. The board has also granted a fellowship award of $2,500 to the American Heart Association with the stipulation that citizens of West Virginia be given preference in using the proceeds of the award. It has been announced that a total of more than $25,000 was collected in the state during the 1951 Heart Fund Drive, an increase of $6,000 over 1950.

Obstetricians and Gynecologists Organize.—Obstetricians and gynecologists in the Charleston area have organized under the name of "The Obstetrical and Gynecological Society of Charleston, West Virginia." Dr. Leo M. Seltzer is president, Dr. George L. Grubb, vice president, and Dr. Frederick H. Dobbs, secretary. Meetings will be held in the library of the West Virginia State Medical Association on the second Thursday in each month from October through May. The objects of the society are to create better understanding between doctors practicing obstetrics and gynecology, to disseminate information concerning new and modern concepts relative to this field, and to enable members to write and discuss papers of interest to the society.

WISCONSIN

Bardeen Memorial Lectureship.—Dr. Charles Huggins, professor of surgery, University of Chicago Medical School, delivered the Bardeen Memorial Lectureship of Phi Chi at the University of Wisconsin Medical School May 10.

Surgeons Meeting.—The Wisconsin section of the U. S. chapter of the International College of Surgeons met June 2 in Marshfield. Featured was an operative surgical clinic. Six papers were presented in the afternoon, and Dr. Arnold S. Jackson, Madison, reported on the meeting of the international college in Florence, Italy. At the evening session Dr. Durand Smith, Chicago, spoke on radiation injury to the bowel, and Dr. William M. McMillan, Chicago, on pitfalls and safeguards in surgery of the colon.

HAWAII

Medical Association Election.—At the recent annual meeting of the Hawaii Territorial Medical Association Dr. Harry L. Arnold Jr., Honolulu, was installed as president. Others elected include Dr. Ransom J. McArthur, Wailuku, president-elect; Dr. Irvin L. Tilden, Honolulu, secretary, and Dr. Edwin K. Chung-Hoon, Honolulu, treasurer. The secretary and treasurer are elected for three years. Dr. Tilden and Dr. Chung-Hoon are now serving the last year of their terms.

GENERAL

New Executive Director for National Foundation.—Mr. Raymond H. Barrows, San Francisco, vice president and manager of the Pacific Area of the American Red Cross, became executive director of the National Foundation for Infantile Paralysis June 1. Mr. Barrows succeeds Mr. Joe W. Savage, executive director since January, 1946. Mr. Barrows joined the Red Cross as assistant director of disaster relief in the Midwestern Area Office at St. Louis in July, 1941, and became director of that service before he was transferred to the Pacific Area office.

Alumni to Finance Medical School History.—A project to bring up to date the history of the Long Island College of Medicine has been undertaken by the alumni association of the college. To finance the project the association is asking for a prepublication sale of copies at $10 each. This second volume is to cover the years 1900 through 1950 and will contain a complete biographical sketch of each graduate. It is to contain about 325 pages and will be completed in 12 to 18 months. Checks payable to the treasurer of the alumni association of the Long Island College of Medicine should be sent to 350 Henry St., Brooklyn 2.

Southern Anesthesiologists Meet.—The Southern Society of Anesthesiologists at their annual meeting in Louisville in April chose Dr. Ralph M. S. Barrett, St. Louis, president-elect; Dr. John Adriani, New Orleans, vice president; Dr. David A. Davis, Augusta, Ga., secretary-treasurer. Dr. Donald Stubbs, Washington, D. C., is the new president. Among the speakers on the program were: Dr. David M. Little Jr., New Haven, Conn.; Dr. Charles R. Stephen, Durham, N. C., and Drs. Charles R. Allen and Harvey C. Slocum of Galveston, Texas. Dr. Fred Williams, Louisville, president of the society, presided at the business session.

Report on Research on Hypertension.—The American Foundation for High Blood Pressure has recently published "Research Progress Report," which lists 19 research projects in the field of hypertension and arteriosclerosis that were supported by the foundation in 1949 and 1950 at a total outlay of $112,522. The American Foundation for High Blood Pressure on Jan. 1, 1950, joined with the American Heart Association and then became its Council for High Blood Pressure Research. In this new affiliation the council continues to operate as did the foundation. The administrative office address of the council is 705 Marion Building, Cleveland 13. Dr. Alva Bradley is president.

Award in Orthopedic Surgery.—A prize of $1,000 donated by the Kappa Delta sorority may be awarded annually by the American Academy of Orthopaedic Surgeons for the best research related to orthopedic surgery and performed in the United States. This research must be presented to the committee on scientific investigation of the American Academy of Orthopaedic Surgeons before Nov. 1. Researchers interested in competing for this prize are requested to secure further information from Dr. Austin T. Moore, Gervais and Pickens Sts., Columbia 5, S. C., chairman of the award committee for 1951.

American Neurological Association.—The American Neurological Association will hold its annual meeting June 18-20 at the Hotel Claridge, Atlantic City, N. J., under the presidency of Dr. Wilder G. Penfield, Montreal, Canada. The program will open with a symposium in which the speakers will be:

Gerhardt Von Bonin, Chicago, Phylogenesis of the Human Cerebral Cortex.
Horace W. Magoun, Los Angeles, An Activating System in the Brain Stem.
Herbert H. Jasper, Mr. Cosimo Ajmone Marsan, Julius Stoll Jr., Montreal, Cortifugal Projections to the Brain Stem.
Stanley Cobb, Boston, On the Nature and Locus of Mind.
Wilder G. Penfield, Montreal, Human Memory Mechanisms.

Tele-Clinics.—Wyeth, Inc., Philadelphia, has undertaken a motion picture educational program to bring to medical personnel who are unable to attend distant professional meetings abstracts of scientific papers presented at such meetings and views of highlights of these assemblies. Tele-Clinic No. 2 was a sound motion picture report of the annual meeting of the American Academy of General Practice in San Francisco in March. The preview presentation was held at the Palmer House, Chicago, May 26 on invitation of the American Academy of General Practice. This production is a 35-minute, 16 mm. black-and-white sound film of which 55 prints will be made available to medical societies, hospitals, nurses groups, and other medical organizations. Tele-Clinic No. 1, released last November, featured the proceedings of the fourth general assembly of the World Medical Association held in New York and has been seen by more than 30,000 doctors throughout the United States.

National Medical Council Formed.—This council was formed in New Haven, Conn., April 20 to work with the Yale Center of Alcoholic Studies on rehabilitation of the problem drinkers in industry, estimated to exceed 2 million. Dr. John J. Wittmer,[*] assistant vice president of the Consolidated Edison Company of New York, Inc., was named chairman of the council. The impact of alcoholism on manpower during national mobilization was the factor prompting the formation of the group. Selden D. Bacon, director of the Yale center, said the council had been approved by the medical heads of leading business and industrial concerns including E. I. du Pont de Nemours & Co., Esso Standard Oil Company, General Motors Corporation, R. H. Macy, Metropolitan Life Insurance Company, and the National Broadcasting Company, Inc.

Plastic Surgery Awards.—The foundation of the American Society of Plastic and Reconstructive Surgery offers junior and senior awards for original contributions in plastic surgery. The junior award is two scholarships in plastic surgery of six and three months respectively. The contest is open to plastic surgeons who have been in the specialty no longer than five years. The senior award will be given for the best essay on "Mass Treatment of Burns in Atomic Warfare." Winning essays will appear on the program of the forthcoming annual meeting of the society to be held at Colorado Springs, Colo., Oct. 31-Nov. 2. Entries must be received by the chairman not later than Aug. 15. For information address the Award Committee, % Jacques W. Maliniac, M.D., 11 East 68th St., New York 21.

Research in Blood Diseases.—The Hematology Research Foundation invites applications for the Ruth Reader Fellowship and the Robert L. Goldblatt Fellowship for research in blood diseases in the academic year 1951-1952. The stipend for each fellowship is $1,500 per year with option to renew. This offer is made to workers of any race or creed in the United States. Applications must be submitted no later than July 15 to Hematology Research Foundation, 72 E. 11th St., Chicago 5. Nine copies of the application are requested. Forms are available on request. Awards will be announced by the medical advisory council in July or August this year. The council will choose the applicants on the basis of merit and will also choose the institution in Chicago in which the work is to be done.

World Health Organization Fellowships.—More than 250 fellowships for advanced study will be awarded this year by the World Health Organization to medical and allied personnel throughout the world. Technical and teaching personnel from WHO member states with at least two years of experience in the field in which the fellowship is sought are eligible for the awards. Applications are made to WHO through the applicant's government. The World Health Organization has already awarded about 800 fellowships in fields including public health administration, communicable diseases, nursing, maternal and child health, internal medicine and surgery. The Pan American Sanitary Bureau, regional office of WHO, awards from its own budget additional fellowships for public health trainees in the Americas. During the past year the bureau granted some 35 fellowships for studies extending from several weeks to a full academic year. This is in addition to the financing by the bureau during 1950 of shorter-term training courses for more than 80 men and women in serological laboratories and a public health nursing workshop.

School of Tuberculosis.—The 37th session of the Trudeau School of Tuberculosis was held at Saranac Lake, N. Y., April 30-May 25. This school has been supported since 1939 by the Lillia Babbitt Hyde Foundation and is intended for physicians who wish to prepare themselves for sanatorium or public health service or those who desire a postgraduate course in diseases of the lungs. The program presents the essentials of history, etiology, epidemiology, pathology, diagnosis, prognosis, and treatment. In addition to daily discussions, classes, and clinics, there were evening lectures by Dr. Honore Smith of Oxford, England, on the "Treatment of Tuberculosis Meningitis"; by Dr. Herman E. Hilleboe, New York State Health Commissioner, on "World Problems in Tuberculosis"; by Dr. Maurice Costello, clinical professor of dermatology and syphilology, New York University College of Medicine, on "Tuberculosis of the Skin"; by Dr. Averill A. Liebow, associate professor of pathology, Yale University College of Medicine, on "Aspects of the Pulmonary Circulation in Disease," and by Dr. Frank R. Ferlaino, medical director, General Motors Corporation, New York, on "Tuberculosis as it Occurs in Industrial Workers."

---

[*] Dr. Wittmer died May 19.

Predoctoral Fellowships.—The National Foundation for Infantile Paralysis has announced a new type of short-term predoctoral fellowships for undergraduate medical students interested in research in medicine and the related biological and physical sciences. The fellowships cover a minimum of two months' experience in research under the direction of a competent investigator in the laboratories of approved medical schools or research institutes in the United States. Under the plan the dean of each four-year medical school has the privilege of nominating one medical student to receive a fellowship. The National Foundation for Infantile Paralysis will provide a stipend of $400 for each student who qualifies for the summer laboratory study. The new fellowships are administered by the division of professional education with the assistance of a professional committee headed by Dr. Thomas B. Turner, professor of bacteriology at the School of Hygiene and Public Health of Johns Hopkins University School of Medicine, Baltimore. The purpose of the new short-term fellowships is to enable medical students to test their desires and determine their aptitudes to participate in research in medicine and related biological sciences at an early stage in their professional careers.

Child Mortality Rates.—Conquest of disease has reduced the mortality at ages 1 to 14 by three fourths since 1930. This is based on the experience among children insured with the Metropolitan Life Insurance Company. The death rate among boys of the insured group dropped from 275.8 per 100,000 in 1930 to 74.7 in 1950 and among the girls from 228.4 per 100,000 to 53.9. At the preschool ages the improvement over the two decades was about four fifths, and the 1950 preschool death rate from all causes combined was lower than the rate from pneumonia alone in 1930. The mortality from the principal communicable diseases of childhood, measles, scarlet fever, whooping cough and diphtheria, fell more than 95 per cent, and the downward trend of the death rate from diarrhea and enteritis was almost as rapid. Reductions of not less than 75 per cent at any of the age periods were recorded for pneumonia, tuberculosis and rheumatic fever. With these shifts in the mortality picture, accidents now constitute the foremost cause of death at every age group for both boys and girls and at 1 to 4 years account for about one death in every three among boys and nearly one in five among girls. A pronounced rise in the recorded mortality from cancer among children has made it now a leading cause of death.

Society Elections.—At the annual meeting of the New Orleans Graduate Medical Assembly March 5-8 Dr. Edgar Hull, New Orleans, was installed as president. Other officers elected for this year include: Dr. Charles B. Odom, New Orleans, president-elect; Dr. Woodard D. Beacham, New Orleans, secretary, and Dr. Robert F. Sharp, New Orleans, treasurer. The 1952 meeting will be held March 10-13, with headquarters at the municipal auditorium.——New officers of the American Psychiatric Association elected during the 107th annual meeting of the association in Cincinnati May 7-11 include: Dr. Leo H. Bartemeier, Detroit, president; Dr. D. Ewen Cameron, Montreal, Canada, president-elect; Dr. R. Finley Gayle Jr., Richmond, Va., secretary, and Dr. Howard W. Potter, Brooklyn, treasurer. ——The American Academy of General Practice at its March meeting in San Francisco installed Dr. Joseph P. Sanders, Shreveport, La., as president and chose Dr. R. B. Robins, Camden, Ark., as president-elect; Dr. Fred A. Humphrey, Fort Collins, Colo., vice president, and Dr. Jack S. DeTar, Milan, Mich., speaker of the house of delegates. The 1952 scientific assembly will be held in Atlantic City, N. J., March 24-27.—— At the annual meeting of the American Institute of Nutrition in Cleveland April 29-May 3 the following officers were elected: Clive M. McCay, Ph.D., New York, president; Paul L. Day, Ph.D., Little Rock, Ark., vice president, and James M. Orten, Ph.D., Detroit, secretary.——The American Otological Society at its meeting at the Hotel Claridge, Atlantic City, N. J., May 11-12 elected the following officers: Dr. Gordon D. Hoople, Syracuse, N. Y., president; Dr. Albert C. Furstenberg, Ann Arbor, Mich., vice president, and Dr. John R. Lindsay, Chicago, secretary-treasurer.——The American Society for Pharmacology and Experimental Therapeutics at its annual meeting in Cleveland April 29-May 3 elected the following officers: Dr. McKeen Cattell, New York, president; Dr. K. K. Chen, Indianapolis, president-elect; Dr. Carl C. Pfeiffer, Chicago, secretary, and Dr. Robert P. Walton, Charleston, S. C., treasurer.

FOREIGN

Anti-Tuberculosis Center Opened in Istanbul.—A new building constructed by the Turkish government to house the World Health Organization Anti-Tuberculosis Center was opened last winter in Istanbul in the presence of the Turkish minister of health, the governor of Istanbul, and representatives of the diplomatic corps. The center had been operating in temporary premises since its foundation last June. The center's primary function is to train medical and health workers in modern anti-tuberculosis methods and to create a unified organization against the disease that would serve as a model for similar services elsewhere. The WHO staff in Istanbul, consisting of a French tuberculosis specialist, an English x-ray technician, and a French nurse, has in eight months given advanced instruction to nearly 300 Turkish doctors and nurses. The new building, which contains five floors and cost $130,000, includes sections for radiography, tuberculin-testing, and BCG-vaccination.

Penicillin Factory in India.—The government of India has announced its decision to accept United Nations assistance in setting up a penicillin factory at an estimated cost of 20 million rupees (4 million dollars). The World Health Organization, as requested by the government of India, will make available technical assistance and training facilities for Indian personnel to an extent of $350,000. The United Nations International Children's Emergency Fund will pay for imported production equipment costing $850,000. The government of India will retain full control over the erection, operation, and maintenance of the factory and its staff and will make available to Indian women and children free supplies of penicillin to the total value of $850,000. It is estimated that a minimum production of 400,000 mega units per month will be reached at the end of two years, rising ultimately to 700,000 mega units.

DEATHS IN OTHER COUNTRIES

Maj. Gen. Sir Percy Tomlinson, who was the medical officer responsible for building up the medical organization of the Middle East Command during World War II, died in Hove, England, March 6, aged 66. He became honorary physician to the King and was elected a fellow of the Royal College of Physicians.——**Professor Martin Mayer** passed away suddenly on Feb. 17 at Caracas, Venezuela, aged 76. For many years he was head of the bacteriological section of the Institut für Schiffs- und Tropenkrankheiten, Hamburg, until he was forced to leave Germany and found refuge at the Universidad Central in Caracas.

CORRECTION

The Heredity of Epilepsy.—In the article by Dr. William G. Lennox on the heredity of epilepsy in THE JOURNAL, June 9, 1951, page 536, in line 12, left-hand column, 7.6 per cent should read 6.4.

MEETINGS

American Electroencephalographic Society, Hotel Claridge, Atlantic City, June 16-17. Dr. John A. Abbott, Massachusetts General Hospital, Boston 14, Secretary.

American Hearing Society, Palmer House, Chicago, June 29. Mrs. Frances E. Lee, 817 Fourteenth St. N.W., Washington 5, D. C., Secretary.

American Neurological Association, Atlantic City, June 18-20. Dr. H. Houston Merritt, 710 W. 168th St., New York 32, Secretary.

American Orthopedic Association, *The Greenbrier, White Sulphur* Springs, W. Va., June 20-23. Dr. C. Leslie Mitchell, Henry Ford Hospital, Detroit 2, Secretary.

Great Falls Medical-Surgical Conference, Great Falls, Montana, June 25-26. Dr. William E. Sullens, Box 1066, Great Falls, Chairman.

Idaho State Medical Association, Sun Valley, June 17-20. Dr. Robert S. McKean, 305 Sun Building, Boise, Secretary.

Maine Medical Association, Poland Spring House, Poland Spring, June 17-19. Dr. Frederick R. Carter, 142 High St., Portland 3, Secretary.

Medical Library Association, Denver, June 28-30. Miss Caroline Riechers, Rush Medical College Library, 1758 W. Harrison St., Chicago 12, Secretary.

Post Graduate Medical Assembly of South Texas, Shamrock Hotel, Houston, Texas, July 23-25. Mrs. W. H. Dahme, 229 Medical Arts Bldg., Houston, Executive Secretary.

Society of Biological Psychiatry, Claridge Hotel, Atlantic City, June 17. Dr. George N. Thompson, 1136 W. Sixth St., Los Angeles 17, Secretary.

West Virginia State Medical Association, The Greenbrier, *White Sulphur* Springs, July 19-21. Mr. Charles Lively, 1031 Quarrier St., Charleston 24, Executive Secretary.

INTERNATIONAL

European Congress on Rheumatism, Barcelona, Spain, Sept. 24-27. Dr. Gunnar Edströn, Lund, *Sweden, Secretary.*

General Practitioners Study Club International, Rome, Italy, Sept. 12-15. Dr. John O'Connell, 10300 Lackland Road, St. Louis 14, Mo., *U. S. A., President.*

International Anesthesia Research Society, London, England, Sept. 3-7. Mr. R. W. Cope, University College Hospital, London W.C.1, England.

International Association of Allergists, Zurich, Switzerland, Sept. 23-29. Prof. A. S. Grumbach, Hygiene Institut der Universitaet Zurich, Gloriastr. 32, Zurich, Switzerland.

International Congress of Anesthesiology, Nursing School of the Salpiettre, 47 Boul de l'Hospital, Paris, France, Sept 20-22. 12 rue de Seine, Paris 6^e, France, Secretariat.

International Congress of Clinical Pathology, London, England, July 16-20. Dr. W. H. McMenemey, Maida Vale Hospital for Nervous Diseases, London W.9, England, Secretary.

International Congress of Gynecology, Maison de la Chimie, Centre Marcellin, Paris, France, June 23-29. Dr. Maurice Fabre, 1, rue Jules-Lefebvre, Paris 9, General Secretary.

International Congress on Industrial Medicine, Instituto Superior Técnico, Lisbon, Portugal, Sept. 9-15. Dr. Luis Guerreiro, Instituto Nacional *do Trabalho e Previdência*, Praça *do Comercio, Lisbon,* Secretary General.

International Congress on Mental Health, Mexico City, Mexico, Dec. 11-19.

International Congress of Military Medicine and Pharmacy, *Paris,* France, June 17-23. Physician General Dutrey, 8, bis, rue de Recollets, Paris 10, Secretary General.

International Gerontological Congress, Hotel Jefferson, St. Louis, Mo., U. S. A., Sept. 9-14. Dr. John E. Kirk, 5600 Arsenal Street, St. Louis 9, Mo., Chairman, Program Committee.

International Hospital Congress, Brussels, Belgium, July 15-21. Capt. J. E. Stone, 10 Old Jewry, London E.C., England, Secretary.

International Poliomyelitis Congress, Copenhagen, *Denmark, Sept.* 3-7. Prof. Dr. Niels Bohr, Statens Seruminstitut, 80 Amager Blvd., Copenhagen S., Denmark, President.

International Society of Surgery, *Paris, France, Sept.* 24-29. Dr. L. Dejardin, 141, rue Belliard, Brussels, Belgium, Secretary General.

International Society for the Welfare of Cripples, Fifth World Congress, Stockholm, *Sweden, Sept.* 9-14. Mr. Donald V. Wilson, 54 E. 64th St., New York 21, N. Y., U. S. A., Executive Director.

Pan Pacific Surgical Association Congress, Honolulu, Hawaii, Nov. 7-19. Dr. Forrest J. Pinkerton, *Suite* 7, Young Bldg., Honolulu, Hawaii, President.

Students' International Clinical Congress, Leyden, Utrecht, Groningen and Amsterdam, Holland, July 10-28. N. A. M. Bergstein, Oude Gracht 143 bis, Utrecht, Holland, Secretary General.

World Confederation for Physicial Therapy, Copenhagen, Denmark, Sept. 7-8.

World Medical Association, *Stockholm, Sweden, Sept. 15-21. Dr. Louis* H. Bauer, 2 E. 103d-St., New York 29, N. Y., U. S. A., Secretary-General.

EXAMINATIONS AND LICENSURE

NATIONAL BOARD OF MEDICAL EXAMINERS

National Board of Medical Examiners: *Parts I and II.* Various Centers. June 18-20, Sept. 5-7 (Part I only). Applications must be filed at least thirty days prior to an examination. Ex. Sec., Mr. E. S. Elwood, 225 S. 15th Street, Philadelphia.

INTERNATIONAL COLLEGE OF SURGEONS

Examinations for Certified Fellowship in the United States Chapter in General and Orthopedic Surgery, Chicago, Aug. 3-4. Sec., Dr. Arnold S. Jackson, 1516 Lake Shore Drive, Chicago 10.

EXAMINING BOARDS IN SPECIALTIES

American Board of Anesthesiology: *Written.* July 20. Given simultaneously in several cities in the United States. Final date for filing application was Jan. 20. *Oral.* Memphis, Oct. 14-17. *Written.* July 18, 1952, Various locations. Final date for filing applications is Jan. 18, 1952. Sec., Dr. Curtiss B. Hickcox, 80 Seymour St., Hartford 15, Conn.

American Board of Internal Medicine: *Written.* Various centers, Oct. 15. *Final date for filing applications* was May 1. *Oral.* The schedule of oral examinations for 1951 has been arranged on a regional basis as follows: June, includes candidates from Beirut, Canada, Canal Zone, Connecticut, Delaware, District of Columbia, Maryland, New Jersey, Ohio, Pennsylvania, Puerto Rico, Rhode Island, Virginia and West Virginia. New York, date to be announced, covering Maine, Massachusetts, New Hampshire, New York and Vermont. San Francisco, date to be announced, covering Arizona, California, Colorado, Idaho, Montana, New Mexico, Oregon, Utah and Washington.

Only candidates who have not taken an oral examination can be admitted under the schedule arranged thus far.

Dates of closing dates for the filing of applications for examinations in New York and San Francisco to be announced.

Oral examinations in the subspecialties will be held at the same time and place and on the same distribution.

Exec. Sec., Dr. William A. Werrell, 1 West Main Street, Madison 3.

American Board of Neurological Surgery: *Oral.* Chicago, Oct. 25-26. *Oral.* Chicago, May 1952. Final date for filing applications for the May 1952 examination is Jan. 1, 1952. Sec., Dr. W. J. German, 789 Howard Ave., New Haven 4, Conn.

American Board of Obstetrics and Gynecology: *Written.* Feb. 1, 1952. Final date for filing applications is Nov 1. Sec., Dr. Paul Titus, 1015 Highland Building, Pittsburgh 6, Pa.

American Board of Ophthalmology: *Written.* Twenty-five centers, Feb. 4-5, 1952. *Oral.* Chicago, October 8-13. Sec., Dr. Edwin B. Dunphy, 56 Ivie Road, Cape Cottage, Maine.

American Board of Orthopaedic Surgery: Final date for filing applications for the 1952 Part II examinations is Aug. 15, 1951. Sec., Dr. Harry A. Sofield, 122 S. Michigan Ave., Chicago 3.

American Board of Otolaryngology: *Oral.* Chicago, Oct. 9-12. *Sec.,* Dr. Dean M. Lierle, University Hospital, Iowa City.

American Board of Pediatrics: *Oral.* Detroit, June 8-10. Buffalo, Oct. 26-28. Ex. Sec., Dr. John McK. Mitchell, 6 Cushman Road, Rosemont, Pa.

American Board of Preventive Medicine: *Written.* San Francisco, October 28. *Oral.* San Francisco, October 29. Sec., Dr. Ernest L. Stebbins, 615 North Wolfe St., Baltimore 5.

American Board of Radiology: *Oral.* Washington, D. C., Sept. 17-22. Sec., Dr. B. R. Kirklin, 102-110 Second Ave., S.W., Rochester, Minn.

American Board of Surgery: *Written.* Various centers, Oct. 1951. Final date for filing applications is July 1. Sec., Dr. J. Stewart Rodman, 225 South 15th Street, Philadelphia.

Board of Throacic Surgery: *Written.* Various parts of the country. Sept. 14, 1951. Final date for filing applications is July 15. Sec., Dr. William M. Tuttle, 1151 Taylor Ave., Detroit 2, Mich.

American Board of Urology: Chicago, Feb. 9-13, 1952. Final date for filing applications is Sept. 1. Sec., Dr. Harry Culver, 314 Corn Exchange Bldg., Minneapolis 15.

DEATHS

Leslie, Frank Elliott ⊕ St. Petersburg, Fla.; born in Woburn, Mass., July 21, 1873; Medical School of Maine, Portland, 1901; commissioned a first lieutenant in the medical corps of the U. S. Army in July, 1917; promoted to captain in October of that year and to major in February, 1918; in September, 1919, was commissioned a surgeon in the U. S. Public Health Service and made senior surgeon in February, 1920; at the time of his retirement in 1943 was manager of the Veterans Administration Memorial Hospital at Mendota, Wis., a position he had held since 1939; specialist certified by the American Board of Psychiatry and Neurology; member of the Maine Medical Association, American Psychiatric Association, National Committee for Mental Hygiene, and the Association of Military Surgeons of the United States; from 1905 to 1917 superintendent of Glenellis Sanitarium in Andover, Maine, where in 1911 he was president of the Oxford County Medical Society; died in the Veterans Administration Center, Bay Pines, March 27, aged 77, of portal cirrhosis and primary carcinoma of the liver.

McClure, Roy Donaldson ⊕ Detroit; born in Bellbrook, Ohio, Jan. 17, 1882; Johns Hopkins University School of Medicine, Baltimore, 1908; assistant in surgery from 1912 to 1914 and instructor in surgery from 1914 to 1916 at his alma mater; specialist certified by the American Board of Surgery; founded and was the first president of the Central Surgical Association; past president of the Detroit Academy of Surgery; fellow of the American Surgical Association, Southern Surgical Association, and the American College of Surgeons, of which he had been a governor; served in the army during World War I as head of an evacuation hospital in France and during World War II as a member of the National Research Council and chairman of the Michigan Medical Advisory Board; creator and first chief of the department of surgery, Henry Ford Hospital; consulting surgeon, Charles Godwin Jennings Hospital; died March 31, aged 69, of arteriosclerotic heart disease.

Crossen, Harry Sturgeon ⊕ St. Louis; born in Centerville, Iowa, Feb. 2, 1869; Washington University School of Medicine, St. Louis, 1892; since 1935 professor emeritus of clinical obstetrics and gynecology at his alma mater, where he was instructor in gynecology from 1901 to 1921, when he became professor of clinical gynecology; member of the American Gynecological Society and the Central Association of Obstetricians and Gynecologists; fellow of the American College of Surgeons; served in France during World War I; affiliated with Barnes, St. Luke's and St. Louis Maternity hospitals; superintendent and surgeon in charge, St. Louis Female Hospital from 1895 to 1899; author of "Diagnosis and Treatment of Diseases of Women," co-author of "Diseases of Women," "Gynecology for Nurses," "Synopsis of Gynecology," "Operative Gynecology," and "Foreign Bodies Left in the Abdomen"; died in Clayton March 10, aged 82, of cerebral hemorrhage.

Richards, Theodore Wright ⊕ medical director, captain, U. S. Navy, retired, Savannah, Ga.; born in Portsmouth, Va., Oct. 8, 1870; Columbian University Medical Department, Washington, D. C., 1893; commissioned an assistant surgeon in the medical department of the Navy Nov. 12, 1894; veteran of the Spanish-American War; served at various naval stations aboard the fleet; in April, 1910, senior medical member of the retirement board; in 1915-1916 served as the medical officer aboard the *USS Maine*; prior to the onset of World War I was liaison officer with the American Red Cross at the Bureau of Medicine and Surgery and officer in charge of personnel for Naval Base Hospital No. 1 in France; during World War I was a special medical advisor to the commanding general of the armed forces for the medical department of the Navy; retired from active duty Nov. 1, 1934, for physical disability; died March 20, aged 80, of heart disease.

Parham, John Calhoun ⊕ medical director, captain, U. S. Navy, retired, San Diego, Calif.; born Oct. 4, 1885; Medical College of Alabama, Mobile, 1906; specialist certified by the American Board of Internal Medicine; entered the medical corps of the U. S. Navy as a lieutenant (jg) on July 7, 1911; served as medical officer aboard the *USS Birmingham* and was also the senior medical officer of the U. S. Naval Base No. 27 at Plymouth, England, during World War I; on the staff of the commander, base force, Pacific, 1936-1937, followed by a two-year tour of duty at the U. S. Naval Hospital, San Diego, Calif.; in 1939-1940 executive officer at the Naval Hospital in Pearl Harbor; retired from active duty Dec. 1, 1940, because of physical disability; died in the U. S. Naval Hospital March 26, aged 65, of cerebral thrombosis and hypertensive cardiovascular disease.

Beckman, William Woods, New York; born in Altoona, Pa., Aug. 22, 1910; Harvard Medical School, Boston, 1935; assistant dean and assistant professor of medicine at the New York University College of Medicine, a unit of the New York University-Bellevue Medical Center; at one time an instructor and associate in medicine at his alma mater; research fellow of the American College of Physicians; member of the American Medical Association; served as intern, resident, assistant in medicine, and assistant physician at Massachusetts General Hospital in Boston; formerly associated with the Rockefeller Institute for Medical Research and the Rockefeller Institute Hospital; participated in the report of the Joint Committee on the Study of Social and Environmental Factors in Medicine published by the Commonwealth Fund; died April 12, aged 40.

Davis, George Edwin ⊕ New York; born in Harrodsburg, Ky., Feb. 18, 1866; Bellevue Hospital Medical College, New York, 1889; specialist certified by the American Board of Otolaryngology; formerly emeritus professor of otology at the New York Polyclinic Medical School and Hospital; instructor of otology at the New Post-Graduate Medical School and Hospital from 1908 to 1914; member of the American Academy of Ophthalmology and Otolaryngology; fellow of the American College of Surgeons; chairman of the medical research board of the American Expeditionary Forces during World War I; later retained a captaincy in the Officers Reserve Corps; consulting aural surgeon, Manhattan State Hospital, New York, Central Islip State Hospital, Central Islip, and United Hospital, Port Chester; died March 24, aged 85, of coronary thrombosis.

Anderson, John Birckhead ⊕ Baraboo, Wis.; born in St. Louis in 1869; Washington University School of Medicine, St. Louis, 1892; honorary member of the Washington State Medical Association; for many years city health officer of Spokane, Wash., and later commissioner of health of the state of Washington; during World War I served on the Council of Defense and was a member of the food conservation committee; in 1921 commissioned a senior surgeon in the U. S. Public Health Service reserve; served on the staffs of various Veterans Administration hospitals; at one time chief neuropsychiatrist at the Hines (Ill.) Hospital, where he organized and was chief of the diagnostic center until his retirement in 1938; died March 22, aged 82, of Parkinson's disease and uremia.

Hunt, Robert Walter ⊕ New York; born in Santa Barbara, Calif., July 12, 1904; Stanford University School of Medicine, San Francisco, 1933; assistant clinical professor of urology at New York Medical College, Flower and Fifth Avenue Hospitals; certified by the National Board of Medical Examiners; specialist certified by the American Board of Urology; member of the American Urological Association; fellow of the American College of Surgeons; served during World War II; assistant attending surgeon and from 1935 to 1938 resident in urology at the James Buchanan Brady Foundation of the New York Hospital; director of urology at St. Clare's Hospital, where he died March 31, aged 46, of intracranial hemorrhage.

⊕ Indicates Fellow of the American Medical Association.

Hoffman, Charles Wilbur ⊕ Baltimore; born in Philadelphia, Dec. 19, 1876; Jefferson Medical College of Philadelphia, 1903; formerly on the faculty of Johns Hopkins University School of Medicine and the University of Maryland School of Medicine; served during World War I; as lieutenant colonel in the medical reserve corps, served as surgeon for the Maryland state guard from 1944 until 1948; at one time associated with the U. S. Public Health Service, and was surgical consultant for several local public health hospitals until 1932; affiliated with the Church Home and Infirmary, St. Joseph's, St. Agnes, Mercy, West Baltimore General, and Franklin Square hospitals; died March 15, aged 74, of carcinoma of the bladder.

Sager, Edward Miller ⊕ colonel, MC., U. S. Air Force, retired, Fort Worth, Texas; born in Yeagertown, Pa., Jan. 31, 1901; Medical College of Virginia, Richmond, 1930; entered the Army in 1930; in 1934 was transferred to the Air Force as a flight surgeon; during World War II served as post surgeon at Barksdale and Maxwell fields and as flight surgeon with the 12th Air Force in Italy; won the Bronze Star medal and three battle stars; surgeon with the Eighth Air Force at Carswell Air Force Base; retired from the Air Force Sept. 30, 1949; assistant city health director; died at Carswell Air Base hospital March 19, aged 50, of acute coronary occlusion.

Moore, John Thomas ⊕ Houston, Texas; University of Texas School of Medicine, Galveston, 1896; professor of clinical surgery at Baylor University College of Medicine; member of the Southern Surgical Association; fellow of the American College of Surgeons; past president of the Harris County Medical Society; specialist certified by the American Board of Surgery; served during World War I; consulting surgeon, Hermann and Methodist hospitals; affiliated with Jefferson Davis Hospital; received the honorary degree of doctor of science from Texas Christian University, Fort Worth; died March 18, aged 86, of coronary thrombosis.

Bowen, John Thomas ⊕ Clearwater, Fla.; University of Pennsylvania School of Medicine, Philadelphia, 1910; served during World War I; on the staff of the Morton Plant Hospital, where he died March 16, aged 75, of coronary thrombosis and arteriosclerosis.

Bowers, George Francis Haskell ⊕ Newton, Mass.; Harvard Medical School, Boston, 1911; member of the New England Pediatric Society; died in Newton-Wellesley Hospital, Newton Lower Falls, April 1, aged 67.

Bradt, Elizabeth Gilchrist, Castile, N. Y.; Boston University School of Medicine, 1915; died in Wyoming County Community Hospital, Warsaw, April 4, aged 61, of multiple sclerosis.

Burch, Albert J., Alpine, Calif.; Fort Worth (Texas) School of Medicine, Medical Department of Fort Worth University, 1899; died in La Mesa (Calif.) Hospital April 3, aged 77, of coronary occlusion.

Clayton, John M., West Louisville, Ky.; University of Louisville Medical Department, 1888; member of the American Medical Association; died in Our Lady of Mercy Hospital, Owensboro, April 3, aged 85.

Collins, William David, Hudson, N. Y.; Albany Medical College, 1907; member of the American Medical Association; served as commissioner of health; affiliated with Columbia Memorial Hospital, where he died April 10, aged 67, of heart failure.

Deutsch, Morris I. ⊕ Far Rockaway, N. Y.; University and Bellevue Hospital Medical College, New York, 1914; member of the staff of the Rockaway Beach (N. Y.) Hospital and St. Joseph's Hospital; died April 4, aged 58, of coronary thrombosis.

Dudley, Gustave Beauregard ⊕ Martinsville, Va.; Medical College of Virginia, Richmond, 1918; served during World War I; died April 7, aged 58.

Ferris, Edward Day, Brooklyn; University of the City of New York Medical Department, New York, 1893; member of the American Medical Association; fellow of the American College of Surgeons; member of the Selective Service Board during World War I; on the staff of the Norwegian Lutheran Deaconesses' Home and Hospital, where he died April 5, aged 86.

Fuller, Spencer Sam ⊕ Riverside, Ill.; Rush Medical College, Chicago, 1902; past president of the school board; served as village health commissioner; died April 3, aged 77, of coronary occlusion.

Gardiner, Harry Miller ⊕ Medfield, Mass.; Hahnemann Medical College and Hospital of Philadelphia, 1931; specialist certified by the American Board of Psychiatry and Neurology; member of the American Psychiatric Association and the New England Society of Psychiatry; served during World War II; assistant superintendent of Medfield State Hospital; died in Baker Memorial Hospital, Boston, April 3, aged 46, of cardiac hypertrophy, hypertension, and nephrosis.

Gibson, John Francis, Olympia, Wash.; University of Texas School of Medicine, Galveston, 1906; specialist certified by the American Board of Ophthalmology and the American Board of Otolaryngology; on the staff of St. Peter's Hospital; died April 2, aged 70.

Gulliver, Francis Daniel ⊕ New York; Columbia University College of Physicians and Surgeons, New York, 1903; affiliated with St. Vincent's Hospital; died April 12, aged 72, of neoplasm.

Johnson, James Paton, Dallas, Texas; Barnes Medical College, St. Louis, 1904; died in Baylor University Hospital March 27, aged 74, of acute cardiac infarction.

Johnston, Walter, Seattle; Jefferson Medical College of Philadelphia, 1887; died March 24, aged 88, of arteriosclerotic heart disease.

Kaveney, Irving Edward ⊕ Port Angeles, Wash.; University of Illinois College of Medicine, Chicago, 1931; served during World War II; died recently, aged 46.

Kinloch, Everett Starke, Troy, N. Y.; Albany (N. Y.) Medical College, 1895; died March 17, aged 82, of right hemiplegia.

Kyser, James Allen, Madison, Ala.; Tulane University of Louisiana, New Orleans, 1911; member of the American Medical Association; chairman of the Farmers & Merchants Bank; died March 11, aged 70, of cerebral hemorrhage.

Maurer, Frederick Henry ⊕ Peoria, Ill.; Rush Medical College, Chicago, 1915; specialist certified by the American Board of Pediatrics; member of the American Academy of Pediatrics, American Association of Physicians and Surgeons, Central Illinois Pediatric Society, and Alpha Omega Alpha; member and past president of the Peoria Medical Society; served during World War I; member and past president of the St. Francis Hospital staff; died April 22, aged 60, of coronary thrombosis.

Montgomery, Charles William, Pasadena, Calif.; Kentucky School of Medicine, Louisville, 1892; also a druggist; died March 13, aged 82.

Mooney, Charles Neil, Oakland, Calif.; Cooper Medical College, San Francisco, 1906; died in San Francisco April 4, aged 68, of tuberculosis.

Morton, Andrew Wade ⊕ San Francisco; University of Tennessee Medical Department, Nashville, 1892; died March 26, aged 82, of coronary occlusion.

Myers, John George Leonard, Bloomingdale, Ind.; Medical College of Indiana, Indianapolis, 1884; died April 1, aged 93.

Neumann, William Henry ⊕ Sheboygan, Wis.; Northwestern University Medical School, Chicago, 1904; specialist certified by the American Board of Otolaryngology; member of the American Academy of Ophthalmology and Otolaryngology; fellow of the American College of Surgeons; on the staffs of Memorial Hospital and St. Nicholas Hospital, where he died March 11, aged 71, of coronary thrombosis.

Norconk, Ward Herman ⊕ Bear Lake, Mich.; Chicago College of Medicine and Surgery, 1917; past president of the Manistee County Medical Society; served during World War I; affiliated with Mercy Hospital and Sanitarium, where he died March 29, aged 59, of coronary thrombosis.

O'Connor, Charles Emmett, Washington, D. C.; Georgetown University School of Medicine, Washington, D. C., 1895; retired medical officer of the department of interior; died March 29, aged 83.

Oertel, Henry Benjamin, Kissimmee, Fla.; University of Georgia School of Medicine, Augusta, 1901; member of the American Medical Association; died recently, aged 76.

Parnell, Charles Nicholas, Maplesville, Ala.; Medical College of Alabama, Mobile, 1891; member of the American Medical Association; died April 5, aged 84, of senile dementia and diabetes mellitus.

Pike, Walter Franklin, Sonora, Calif.; Denver and Gross College of Medicine, 1903; died March 25, aged 74.

Pratt, Charles Augustus ⊕ New Bedford, Mass.; Harvard Medical School, Boston, 1891; an Associate Fellow of the American Medical Association; honorary trustee and past president of the medical staff of St. Luke's Hospital; died April 3, aged 88, of terminal pneumonitis, diabetes mellitus, and arteriosclerosis.

Rieser, Sidney Loeb ⊕ New York; University and Bellevue Hospital Medical College, New York, 1916; on the staffs of Sydenham and Doctors hospitals; died April 12, aged 57, of coronary thrombosis.

Sargent, Laurrie Dodd, Washington, Pa.; Western Pennsylvania Medical College, Pittsburgh, 1903; past president of the Washington County Medical Society; specialist certified by the American Board of Internal Medicine; fellow of the American College of Physicians and the National Tuberculosis Association; served during World War I; trustee of the Woodville (Pa.) State Hospital; affiliated with Hillsview Sanitarium and Washington Hospital, where he died April 6, aged 72, of coronary thrombosis.

Schermerhorn, John Ralph ⊕ Schenectady, N. Y.; Albany Medical College, 1905; member of the American Academy of Dermatology and Syphilology; past president of the Schenectady County Medical Society; affiliated with Ellis Hospital; died in Tampa, Fla., March 28, aged 71.

Schmidt, Frederick Hermes, Woodstock, Ill.; Chicago College of Medicine and Surgery, 1911; member of the American Medical Association; died near Genoa City, Wis., March 22, aged 68, of injuries received in an automobile accident.

Schwankhaus, Paul H., Louisville, Ky.; University of Louisville Medical Department, 1898; on the staffs of Deaconess and SS Mary and Elizabeth hospitals; died March 13, aged 72, of hypertensive cardiovascular disease.

Siler, Levi Steely, Corbin, Ky.; Hospital College of Medicine, Louisville, 1903; member of the American Medical Association; died March 21, aged 73, of multiple sclerosis.

Skarstrom, William, Duxbury, Mass.; Harvard Medical School, Boston, 1901; professor emeritus of hygiene and physical education at Wellesley (Mass.) College; died March 24, aged 81.

Slattery, George Norbert ⊕ New York; University and Bellevue Hospital Medical College, New York, 1909; formerly clinical assistant professor of medicine at his alma mater; at one time house physician for the Metropolitan Opera Company; died March 27, aged 69, of cardiac disease.

Smith, Rolla Lamar, Philadelphia; University of Pennsylvania Department of Medicine, Philadelphia, 1889; member of the American Medical Association; died March 17, aged 84, of pneumonia.

Sooy, John Lynch, Pleasantville, N. J.; College of Physicians and Surgeons, Baltimore, 1912; died in Atlantic City (N. J.) Hospital March 29, aged 64, of carcinoma of the pancreas.

Spier, Oscar Agnew, New York; Eclectic Medical College of the City of New York, 1901; served in France during World War I; died March 8, aged 69, of coronary thrombosis.

Spyker, John Huston, Decatur, Ill.; College of Physicians and Surgeons, Baltimore, 1902; member of the American Medical Association; affiliated with Decatur and Macon County Hospital; died March 25, aged 74, of heart disease.

Steedle, Joseph G., McKees Rocks, Pa.; Western Pennsylvania Medical College, Pittsburgh, 1902; member of the American Medical Association; served in the state legislature; for one term burgess of McKees Rocks; on the staff of the Ohio Valley General Hospital; died March 8, aged 70, of coronary occlusion.

Steele, Robert Lowry, McKeesport, Pa.; University of Pittsburgh School of Medicine, 1903; member of the American Medical Association; died April 3, aged 74, of carcinoma of the prostate.

Stephenson, Frank Halleck, Cazenovia, N. Y.; College of Physicians and Surgeons, medical department of Columbia College, New York, 1878; member of the American Medical Association; for many years affiliated with the Memorial Hospital in Syracuse; died March 8, aged 94, of cerebral arteriosclerosis.

Stiffey, Philip Ellsworth, Columbus, Ohio; Starling-Ohio Medical College, Columbus, 1912; member of the American Medical Association; on the staff of the Grant Hospital; died March 11, aged 67, of heart disease.

Stoddard, James ⊕ Buffalo; L.R.C.P., Edinburgh, L.R.C.S. Edinburgh, and L.R.F.P. & S., Glasgow, 1888; University of Edinburgh Faculty of Medicine, 1892; an Associate Fellow of the American Medical Association; died in Derby, N. Y., April 8, aged 94, of arteriosclerosis.

Stowell, Harold Bishop, Watertown, N. Y.; Albany Medical College, 1895; member of the American Medical Association; died in the House of the Good Samaritan March 16, aged 77, of heart disease following pneumonia.

Stuart, Albert Berry, Cloquet, Minn.; University of Nebraska College of Medicine, Omaha, 1904; member of the American Medical Association; served in France during World War I; for many years chairman of the library board; member of the fire commission; affiliated with St. Luke's Hospital in Duluth; died March 21, aged 68, of cerebral hemorrhage.

Summerbell, Ferris, Fallon, Nev.; Baltimore Medical College, 1905; member of the American Medical Association; died in Churchill County Hospital in Churchill March 2, aged 73, of pulmonary edema and cardiac decompensation.

Swan, Charles Arthur ⊕ Cleveland; Western Reserve University School of Medicine, Cleveland, 1916; member of the American Association of Industrial Physicians and Surgeons; affiliated with Lakeside, Charity, and St. Luke's hospitals; medical director of the Standard Oil Company and Yellow Cab Company; for many years medical director of the Halle Brothers Department Store; chief medical examiner for the Equitable Life Assurance Society of the United States; died in Bradenton, Fla., April 4, aged 59, of injuries received in an automobile accident.

Thrasher, A. Wade, Los Angeles; Central College of Physicians and Surgeons, Indianapolis, 1894; formerly on the staff of Methodist Hospital, Indianapolis; died March 29, aged 78, of cardiac decompensation.

Tupper, Virgil L. ⊕ Bay City, Mich.; Jefferson Medical College of Philadelphia, 1896; an Associate Fellow of the American Medical Association; past president of the Bay County Medical Society; fellow of the American College of Surgeons; on the staff of Mercy Hospital; died April 13, aged 82.

Vates, Charles William ⊕ Pittsburgh; University of Pittsburgh School of Medicine, 1912; served overseas during World War I; member of the staff of South Side Hospital and on the visiting staff of Magee Hospital; served as director of schools and director and vice president of the First Federal Savings and Loan Association of Mount Oliver; died April 2, aged 66, of coronary occlusion.

Weinberg, Frederick Julius, New York; Johann Wolfgang Goethe-Universität Medizinische Fakultät, Frankfurt-am-Main, Prussia, Germany, 1924; died March 12, aged 57.

Wickstrom, Albert M. ⊕ Chicago; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1906; died in the Salvation Army Hospital April 1, aged 78, of carcinoma of the prostate.

Williamson, George H. ⊕ Neenah, Wis.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1895; past president of the Winnebago County Medical Society; supreme medical examiner emeritus for the Equitable Reserve Association; a director of the Wisconsin Anti-Tuberculosis Association; for many years chairman of the Neenah Health Council; died April 2, aged 82.

GOVERNMENT SERVICES

ARMY

Gastro-enteritis.—The Office of the Army Surgeon General reports that in the outbreak of acute gastro-enteritis at Fort Meade, Md., on May 17, a total of 389 men were sick enough to report to the dispensary, and 10 are known to have become ill on a bus after leaving the post. Of the 389 men, 102 were hospitalized. Epidemiological evidence indicates that corned beef hash served at breakfast May 17 was the source of infection. The incubation period varied from one to six hours. A staphylococcus was isolated from vomitus, but this organism has not yet been incriminated as a toxin producer.

An outbreak of gastro-enteritis that occurred among Air Force personnel stationed in the Pentagon Building May 17 is still under investigation. The Bolling Air Force Base Laboratory reports that a staphylococcus has been isolated from remnants of ham that was served. It has not been determined whether the organism is a toxin producer.

Award and Commendation.—The Legion of Merit was recently awarded to Col. Robert C. Robertson, Chattanooga, Tenn. The citation reads in part as follows:

"Colonel Robert C. Robertson, (then Lieutenant Colonel), Medical Corps, performed exceptionally meritorious service as Orthopaedic Consultant, Office of the Chief Surgeon, United States Army Forces, Pacific Ocean Area, from March 1942 to September 1945. He greatly assisted in the formulation of policies and the selection, training and supervision of personnel in connection with the treatment of orthopaedic casualties in the theater. Colonel Robertson carried on his mission of supervision and training within the combat area hospitals and down through the chain of evacuation, to the battalion aid stations of the United States Army Forces engaged in Saipan, Guam, Leyte and Okinawa. Through his outstanding professional skill, leadership, understanding and tact, he made a material contribution to the mission of the Medical Department in the Pacific Ocean Area."

Personal.—Maj. Gen. George E. Armstrong, the new Surgeon General, was named outstanding medical alumnus of 1951 by the Indiana University School of Medicine, Indianapolis, at the annual alumni day May 9. General Armstrong delivered an address on the "Armed Services and the Physician."

AIR FORCE

Award Given Colonel Mashburn.—Col. Neely C. Mashburn, MC, U. S. Air Force, retired, who devised an apparatus 25 years ago that is still being used to predict flying aptitude in cadet applicants, is the 1951 recipient of the Raymond F. Longacre Award of the Aero Medical Association. Used extensively during and since World War II, the complex coordination test has proved one of the most reliable means to predict success in pilot training. It has been given more than a million applicants. Despite the great differences in training methods as well as in the size and speed of aircraft used now and those of 25 years ago, the Mashburn test remains highly predictive.

The Longacre Award, named in commemoration of a pioneer Air Force flight surgeon, is given annually for outstanding accomplishment in the psychiatric and psychological aspects of aviation medicine. Colonel Mashburn, who retired in 1948 after more than 31 years of active service, now lives in San Antonio, Texas.

New Preventive Medicine Chief.—Col. Fratis L. Duff has assumed the duties as chief of the Preventive Medicine Division, Office of the Surgeon General, U. S. Air Force. Colonel Duff received his master's degree in public health at Johns Hopkins University in 1950, and he has been certified by the American Board of Preventive Medicine and Public Health as a specialist; he is presently completing his doctorate in this field. Practical experience includes three years of field work in Egypt and Japan; five years of teaching tropical medicine and parasitology at the School of Aviation Medicine, and two years as sanitary engineer for the Public Health Department in his home city, Lawton, Okla.

Personal.—At the recent meeting of the Aero Medical Association in Denver Maj. Gen. Harry G. Armstrong, Surgeon General of the U. S. Air Force, was installed as president, while Maj. Gen. Dan C. Ogle, Deputy Surgeon General, U. S. Air Force, was elected vice president. Col. Robert J. Benford (MC) of the Air Force, headquarters Air Research and Development Command, was reelected to the executive committee. The next meeting will be held in Washington, D. C., next spring.

Aero Medical Laboratory.—The U. S. Aero Medical Laboratory will participate in a joint wet-cold field test at Cold Bay, Alaska, next September. The test will be coordinated with the Alaskan Air Command. Invitations to participate have been sent to the Royal Canadian Air Force and Royal Air Force.

VETERANS ADMINISTRATION

Service for Veterans Who Stutter.—Veterans who stutter may be helped through a nine-week course offered under the G.I. educational bill by Northwestern University, Evanston, Ill. The course, which is called an "Intensive Group Stuttering Project," is a program of both individual and group therapy procedures by the staff of the speech clinic. The program has helped many veterans since its inception in 1949. Veterans who seek help through this program must complete eligibility processing and be enrolled on or before July 25, 1951. No college "credit" in course hours is given. To apply for the course, the veteran must come to the clinic for an interview, at which time his needs will be assessed, and, if eligible, his eligibility processing will be initiated. Receipt of eligibility papers from the VA completes enrolment. No other steps need be taken beyond bringing these papers to the clinic. Contact Charles R. Elliott, Speech Clinic, Northwestern University, Evanston, Ill. Phone Evanston, University 4-1900, extension 247.

National Advisory Committee.—Representatives of 41 national organizations affiliated with the Veterans Administration voluntary service national advisory committee met at the VA hospital in Framingham, Mass., May 24-25 to observe volunteer workers at their tasks in helping care for patients. The visitors observed a demonstration by hospital staff members of the team approach to the so-called "whole person" care and treatment program at the opening session. The delegates observed the work of volunteers in all phases of hospital work.

The committee heard addresses by Carl R. Gray Jr., administrator of veterans affairs, and Dr. Joel T. Boone, vice admiral (MC, USN), retired, the VA's chief medical director. A part of the session was devoted to an evaluation of the volunteers' work at the hospital. Volunteer hospital workers, the national and local hospital advisory committees, the hospital staff, and VA central office staff members attending participated in the discussion.

Hospital News.—On May 10 the staff of the Veterans Administration hospital at Outwood, Ky., was addressed by Dr. A. J. Miller, professor of pathology, University of Louisville School of Medicine, on "Tumors of the Kidney." Dr. E. L. Pirkey, professor of radiology, addressed the group May 17 on "Medical Uses of Radioisotopes."

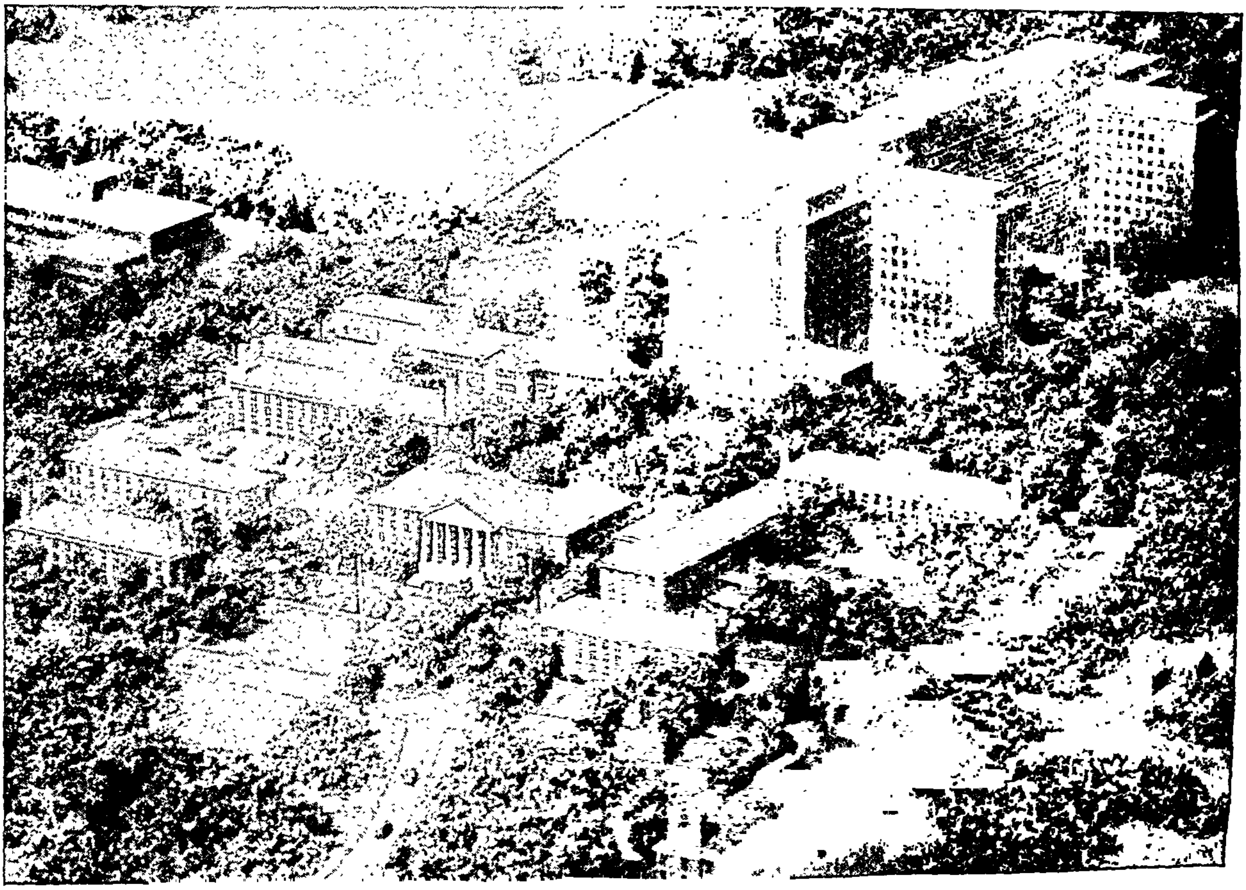
PUBLIC HEALTH SERVICE

New Clinical Center for Medical Research.—The President will lay the cornerstone of the Public Health Service's new Clinical Center for Medical Research at Bethesda, Md., June 22. A large number of medical scientists and educators are expected to attend the cornerstone ceremonies.

This unique 500-bed addition to the National Institutes of Health is now under construction. Authorized by Congress in 1947, it was started in 1948 and will be completed in the latter part of 1952 at a cost of about 40 million dollars. A limited number of special patients will be admitted by January, 1953, and full operation will be reached about a year later.

Dr. Leonard A. Scheele, Surgeon General of the Public Health Service, described the Clinical Center as "the only combined laboratory-hospital in the world especially designed for research on a group of important chronic diseases—cancer, heart disease, mental, metabolic and neurological diseases, and blindness." Dr. Scheele said that close coordination of basic and clinical research within the walls of a single hospital will help reduce the time lag between a laboratory discovery and its use for the benefit of patients. He said the new center, unlike the average hospital, will have twice as much space for laboratory research as for patient care. Bed and laboratory facilities will be set aside, floor by floor, for the study of each of the diseases with which the National Institutes of Health is specifically concerned. Restriction of patients to those having the few but extremely important diseases undergoing investigation will permit scientists to study in a short time relatively large numbers of patients with the same disease.

Dr. Scheele emphasized that while the center will be devoted to research, the welfare of the patient will be of primary importance. The individual patient will receive, according to his needs, the best medical care, including surgery, nursing, psychiatry, and all other specialized services.



The new Clinical Center for Medical Research.

Dr. John A. Trautman, now medical officer in charge of the Marine Hospital, Staten Island, N. Y., will be the director of the new Clinical Center for Medical Research. A career officer with 22 years in the Public Health Service, Dr. Trautman brings to his new post wide experience both as a hospital administrator and as a clinical investigator.

Hill-Burton Act Hospitals.—The Public Health Service on March 31, 1951, had approved 1,524 applications for the construction of hospitals, health centers, and related facilities under the Hill-Burton Hospital Survey and Construction Act. The estimated cost of the construction is $1,105,510,000, of which the federal share is about $402,115,000. The projects would add 73,000 beds and 233 health centers to this country's medical care facilities. Construction projects that have been completed and are now in operation total 429. These provide nearly 13,000 of the 73,000 beds that will be made available by approved projects.

The following lists show the states with the largest number of approved projects, those adding the largest number of beds, and those with more than 500 beds provided by projects completed and in operation.

States with 50 or more approved projects: South Carolina, 106; Texas, 88; Georgia, 86; North Carolina, 81; Mississippi, 73; New York, 63; Oklahoma, 59; Ohio, 52, and Louisiana, 52.

States with approved projects providing over 2,500 beds: Texas, 5,057; Ohio, 3,526; North Carolina, 3,462; New York, 3,389; Pennsylvania, 3,086; Oklahoma, 2,973; Puerto Rico, 2,909; New Jersey, 2,824, and Kentucky, 2,545.

States with over 500 beds in completed projects: Texas, 1,132; North Carolina, 934; Kentucky, 707; Tennessee, 612; Georgia, 603; Florida, 555; Mississippi, 554, and Oklahoma, 512.

Seventy-four of the 233 approved health center projects have been completed and are in operation. Mississippi has 23, South Carolina 22 and Georgia 15. Other states have but one or two completed projects.

AUSTRALIA

Encephalitis Epidemics in Australia.—Epidemics of severe human encephalitis are in progress in various parts of this continent. The evidence indicates that they are due to the Japanese B type of encephalitis virus; horses and dogs are likely reservoirs; a mosquito is the possible vector, and migratory birds may be the means of introduction into the country.

There have been previous epidemics of encephalitis in Australia—1917-1918, 1922, and 1925. The present epidemic showed itself early this year in an area known as the Murray Valley, in North Victoria. This area is used for irrigated agriculture, and mosquitoes are prevalent due to the abundant water.

The typical case history is one of commencing irritability and headache, followed by nausea and vomiting with temperature to about 105 F. A moderate degree of neck stiffness then develops, with some irrationality, even to violence. Tremors and localized spasticity are common. Coma then develops, associated with muscle flaccidity. Some die, and others slowly improve and completely recover.

Typical laboratory findings in the spinal fluid are as follows: 100 cells per cubic millimeter (range 20-750) comprising polymorphonuclear leukocytes, lymphocytes, and up to 10% monocytes. Protein content is slightly increased. Chlorides are decreased, and sugar is normal or slightly decreased. Children below 12 years predominated in the age distribution, but all ages are susceptible. The majority were males.

Frozen central nervous system tissue was brought to the Walter and Eliza Hall Institute of Medical Research in Melbourne, and emulsions were inoculated into developing chick embryos and laboratory animals. After five days, on second passage, focal lesions were produced on the chorioallantoic membrane of the chick embryo. When this was transferred to the brains of mice, rapidly fatal encephalitis developed.

It was found that the focal lesions on the chick membrane provided a valuable antigen for the complement-fixation test. Nearly all (19 of 21) of the convalescent encephalitis patients in the area showed high titer antibody in their blood serum. Results in 10% of 109 contacts were positive. Antibodies were present in 11 out of 19 horses and two of four dogs in the area affected. But results were negative in the serums of 53 sheep, 17 cows, 5 ducks, and 16 pigs.

The serums of the staff of the Hall Institute did not contain antibodies. Serum in isolated cases of encephalitis in Melbourne also failed to show antibodies.

A guinea pig serum prepared against Japanese encephalitis B reacted strongly in a complement-fixation test with the virus isolated in this epidemic. This serum had been prepared in the Commonwealth Serum Laboratories. From a study of the other properties of the virus, the clinical and epidemiological characters, and the serological evidence, there is a strong assumption that the virus isolated is identical with that of Japanese B encephalitis.

By an unfortunate coincidence, this Murray Valley area had been recently the venue of a successful transmission experiment of the virus of myxomatosis among wild rabbits, the vector also being the mosquito. (The wild rabbit is a serious pest in Australia.) Some public alarm was caused by the association of the two epidemics, and the use of rabbit flesh as a food fell into serious disfavor. Fears were mostly allayed, however, after the public statement by Sir F. M. Burnet, director of the Hall Institute and research professor of experimental medicine in the University of Melbourne, that there was no relation between the two diseases. The encephalitis virus produces no symptoms or lesions in rabbits.

Two thousand miles away from the Murray Valley, on Mornington Island in the Gulf of Carpenteria (Northern Australia), serums from aboriginal patients suffering from encephalitis have been shown to contain complement-fixing antibodies active against the Murray Valley virus. A field study is in progress by the staff of the Queensland Institute of Medical Research, and serums will be taken, for investigation at the Hall Institute in Melbourne, from every inhabitant of the island and every accessible animal and bird. Sporadic cases in rural Queensland will also be investigated. This outbreak, occurring as it does in a geographic line between Japan and Victoria, lends support to the view that the virus was introduced by migratory birds.

Death of "Flynn of the Inland"—On May 5 occurred the death of a legendary character who devoted his life to the development of medical services in the sparsely populated interior of this country. He was superintendent of the Australian Inland Mission, a position he had held for 40 years. He had seen it grow from a plan drawn with a stick on the sands of Central Australia to a highly efficient service covering a territory equal in area to half of Europe (2 million square miles) and costing $100,000 per year to maintain.

The Very Reverend Dr. John Flynn, O.B.E., ranks with such immortals as Gorgas of Panama, Antle of British Columbia, and Grenfell of Labrador. He was a Presbyterian minister and for the usual term occupied the highest position in that church in Australia, that of moderator-general. His vision and his pioneering spirit transcended that of a denominational dignitary. It is indeed seldom that a man is canonized in his lifetime.

During the period 1912-1928, he had established 13 small hospitals, each staffed by two trained nurses; in May 1928 at Cloncurry, in Western Queensland, the first "Flying Doctor" set out on his rounds. His territory was larger than France. Only two years previously, Alfred Traegar, an electrical engineer of Adelaide, had designed a small wireless set capable of receiving and transmitting voice and Morse code. The power for this is generated by the operator riding a fixed bicycle, the back wheel of which drives a generator. Until radiotelephony could be used, Traegar designed a typewriter keyboard that automatically sent out the letter in Morse code. All the operator had to do was to sit on the bicycle and pedal, then tap out the message on the keyboard of the typewriter. Even that ingenious system was developed to the stage of voice transmission. Before 1939 the cost of a pedal-generated "transceiver" was about £70 ($155), with an annual upkeep cost of $6. A child of 10 could operate it. Up to 500 miles is a normal range. It has been effective over 2,000. This system of communication enables the mother in a remote homestead to "ring up" the doctor and ask his advice. With the aid of the Flying Doctor Medical Chest in every homestead, many common ailments can be treated and emergency care given. It is in overcoming the feeling of isolation that the Flying Doctor serves so well. The service is aptly known as a "Mantle of Safety," because it gives these lonely people an increased feeling of security.

The Flying Doctors are usually given other duties by the government. Dr. Allen Vickers, one of the first of them, had been appointed a police magistrate, protector of aborigines, and mining warden. One day he flew to Marble Bar (the hottest town in Australia) from Port Hedland in the far northwest. During the day, he saw 12 patients, performed two operations, held an inquest, conducted a court case, pulled innumerable teeth, renewed the licenses of five hotels, and granted applications for mining leases and permits for native labor. Then he flew home for dinner in his aerial ambulance.

On another occasion, a dislocated shoulder was reduced by wireless. The doctor was in his surgery at Broken Hill, seated before a microphone. A woman pedalled her transceiver set at Innamincka, 400 miles away. In the room was the injured man sitting on a stool. A police trooper and stockman stood by the man to do the manipulating according to the directions of the doctor, relayed over the woman's shoulder from her position at the set.

The items in these letters are contributed by regular correspondents in the various foreign countries.

"Hold his elbow close to his side. Have you got that? Over to you." "We are holding his elbow close to his side. What next? Over to you."

"Let the other man hold the forearm; do you get the idea? Over to you."

And so it went on, until a grunt from the patient and a dull click from the shoulder made medical history.

John Flynn's dream has not only come true, it has proved itself and has become a permanent part of Australia's medical services. It provides a means whereby the practice of medicine may be carried to a large number of people who cannot efficiently be reached in any other way. On the badge of the Flying Doctor Service are the three words "Medicine, Aviation, Radio."

McGill University in 1940 conferred on John Flynn the honor of doctor of divinity in recognition of his life's work to humanity. In 1933 he was honored by the King with the Order of the British Empire. So far, in no other country of the world has John Flynn's triology of medicine, the airplane, and the radio been associated in such a service to isolated people. This saga of Flynn's is a contribution which Australia offers to other nations to assist them in solving similar problems, which must exist in many countries.

Dropping Medical Supplies from the Air.—In the interests of speedy delivery of perishable medical supplies, such as blood for transfusions and the equipment for its administration, experiments were made in Victoria with various types of dropping equipment. One of the parachutes tested was developed in New Zealand for "chuting" supplies to deer stalkers in the mountains. It is made of sacking, and it is claimed that anyone who can use a bag needle can make one in an hour. The blood bottles (½ liter) were packed in sawdust in a cardboard carton, wrapped in two woolen blankets. This was attached to a sacking parachute. The drop was from 600 feet. Recovery was completely satisfactory.

Similar results were obtained with a full drop in a "storpedoette," invented by Mr. T. R. Morris. This container is made of cardboard, 2 ft. long by 8 in. wide, and shaped like a bomb. It has a pressurized conelike nose which is designed to burst at a pressure of 3,500 lb. The nose is crushed on impact, and this protects the contents of the package.

BELGIUM

Hospitals for the Insane.—There is a tendency toward replacement of the term "insane asylum" by psychiatric clinic or hospital. The psychological reasons in favor of this modification are understandable. However, this change must be simultaneous with reforms to convert all the asylums into institutions of true hospital type. The management of hospitals for the insane needs great basic changes. Guided by these facts, Lamsens, in a presidential address opening the last session of the Society of Mental Medicine of Belgium, traced the history of the Duffel Asylum, near Antwerp. Duffel was a small asylum that could house 600 patients. It was destroyed in 1914, and reconstructed after the war. It was then reserved for chronically ill patients, who numbered only 234 in 1926. In the course of the last 25 years, new services were added—a medico-pedagogical center, a maternity ward, an antituberculosis dispensary, an establishment for children and a school for nurses. The mental patient benefits from the existence of other services which create a therapeutic atmosphere of assistance as well as an environment of transition back to society. Lamsens condemned obsolete therapy, the methods of enforcing isolation, punishment, and the abuse of sedatives, and stressed the importance of occupational therapy.

Exophthalmos Due to Endocrine Disturbances.—The Belgian Society of Ophthalmology devoted an important session to the study of Danis and Mahaux's report on exophthalmos caused by dysendocrisiasis. The authors, in discussing the orbito-ocular symptoms associated with hypothyroidism and hyperthyroidism, emphasize the need of exophthalmometric measurements; certain symptoms, such as the retraction of the upper eyelid, may mislead one into thinking that exophthalmos is present, while others, such as edema of the eyelids, may mask a real exophthalmos. A sudden suppression (by surgical or by medical means) of a hyperthyroid manifestation appears dangerous, since it stimulates hypersecretion of the hypophyseal thyrotropic hormone.

The emergency treatment of malignant exophthalmos may require decompressive orbital trephining or blepharorrhaphy. Some authors believe that "dry" exophthalmic goiter of the Basedow type and malignant edematous exophthalmos have a common basis, differing only quantitatively. The role of the hypophyseal thyrotropic hormone has been clearly established in this condition. This hormone induces a collagen disease characterized by an abnormal increase of mucopolysaccharides in the orbit, which causes orbital edema and degeneration of the eye muscles. Weekers maintains that there are transition forms between "dry" and edematous exophthalmos. In certain cases of thyrotoxicosis, exophthalmos may even be absent.

De Walsche discussed unilateral exophthalmos. True unilateral exophthalmos is said to be very rare. Most of the time, the exophthalmos is more pronounced on only one side. Its existence is ascribed to unknown local factors.

Welders' Disease.—In a paper published in *Médecin d'Usine*, Mignolet ascribed the majority of intoxications observed in 216 welders (blow torch or electric arc) to three main causes: (*a*) the cutting of sheet iron or other metals previously painted with lead colors, galvanized or, more rarely, coated with cadmium, in which case there is real volatilization of toxic metals due to the heat of the blow torch; (*b*) the use of certain rods or electrodes for electric arc welding, the covering of which contains or produces toxic products on combustion; (*c*) gases of combustion, such as carbon monoxide and nitrous gases which accumulate in confined quarters or an ill-ventilated workshop (welding in furnaces, tanks and boilers). The study of the cases observed shows that electric arc welding is definitely more dangerous and harmful than the other soldering procedures. It seems that it is possible to attribute the respiratory and digestive incidents to the fumes caused by welding. Welding shops, especially for electric welding, should be well ventilated especially in the proximity of the electric arc.

Pulmonary Asbestosis.—At the Society of Occupational Medicine, Clerens reported the results observed in 75 cases of asbestosis, presenting a well documented study. Function tests were performed, sputum was examined for asbestos content, and results were then interpreted. However, as in other pneumoconioses, greatest attention should be given to roentgenologic study. Clerens' statistics differ from those published by Anglo-Saxon authors, owing perhaps to the fact that the latter studied mainly workers of the asbestos textile industry, while Clerens was especially interested in fibro-cement workers. A case is reported in which it was concluded, from clinical observation and the results of necropsy, that death was due to cardiac decompensation. Clerens, however, suggested that the case history indicated that pulmonary asbestosis was a possible diagnosis.

Hemostatic Action of Amniotic Fluid.—At the Belgian Society of Clinical Biology, Verstraete discussed the coagulating action of amniotic fluid. The coagulation time of normal blood is shortened to half in the mixtures of one part of amniotic fluid with 25 parts of blood. The amniotic fluid does not contain prothrombin, thrombin or fibrinogen. Its coagulating action seems to be similar to the effect of suspensions of thromboplastin. It is probable that the amniotic fluid possesses the two constituents of thromboplastin (the plasma factor and the cellular factor). The thromboplastin preparation made from the placental tissue is more active, resistant and thermostabile than the extracts prepared from the lung or the brain.

Surgery of Arteries.—At the Belgian Society of Cardiology, Govaerts reported on the results he obtained with embolectomy and endarteriectomy. He made the following conclusions: (*a*) Embolectomy must be performed immediately if severe signs of ischemia appear within a few hours after the accident. On the other hand, if the disturbances are little pronounced, it is preferable to wait for the improvement of the collateral circulation. (*b*) In arterial thrombosis, sympathectomy favoring collateral circulation is indicated. Endarteriectomy is in principle more logical than venous graft, because the anatomic integrity of the vascular system of the extremity is reestablished. Endarteriectomy must be reserved for limited lesions in young persons and should be done under the protection of heparinization.

TURKEY

Kala-Azar in Turkey.—At the 3d Turkish microbiology congress held at Ankara Oct. 4-6, 1948, Prof. Arif Ismet Çetingil of Istanbul University reported on kala-azar in Turkey, the first case of which appeared in Turkish medical literature in 1931. The clinical symptoms resembled those of malaria, but spleen puncture revealed Leishmania donovani. The patient, a girl of 16, was given 32 days of ethylstibamine therapy and recovered. In 1935, Professor Çetingil diagnosed kala-azar (autochthonous) in a second case, in a boy 5 years. The patient was presented at a meeting of the Turkish medical society. In 1935, kala-azar was diagnosed in three cases at the same medical department of the university in children 6 to 7 years old. Extreme splenomegaly, hepatomegaly, and anemia were present in all patients, and sternal and spleen puncture revealed Leishmania. The red blood cell count was two to three million, the white blood cell count 1,900 to 2,400, and the hemoglobin value 30 to 40%. The differential study of the white cells showed 7 transitional mononuclear cells, 44 polymorphonuclear neutrophils, 41 lymphocytes and 8% large monocytes. Results of the formol-gel and Chopra-Gupta tests were strongly positive. There were a great number of freely circulating Leishmania. Every other day these three patients received a 0.05 gm. intravenous injection of ethylstibamine; the dose was gradually increased to 0.3 gm., and the total dose was 1.95 gm. Two patients recovered; the third patient, though given a blood transfusion and pentose nucleotide, died of agranulocytosis.

From 1937 to 1948, Ord. Prof. Ihsan Hilmi Alantar of Istanbul University Children's Hospital treated 25 children, 9 months to 11 years old, for kala-azar. During the same period, 10 children, 2 to 8 years old, were treated for kala-azar by Dr. Ali Sükrü Savli, director of the Istanbul Municipal Hospital (Haseki) children's department; also, Dr. Sirri Halil Aksoy, chief of the Istanbul -Haydar Pasha General Hospital children's department, reported 13 children, 1 to 11 years old, with kala-azar. From 1938 to 1948, Dr. N. Fakaçelli of St. George Hospital, Istanbul -Pera, reported 49 cases, of which 37 were autochthonous kala-azar in children 16 months to 9 years old. In 1945, Prof Muzaffer Chevki Yener, Istanbul University medical department, reported a case of kala-azar in a man of 23. The patient had all the symptoms of kala-azar; Leishmania were recovered from the spleen and the liver, but the sternal puncture was negative. The patient was given ethylstibamine and recovered. This patient, had probably contracted the disease at Manisa, near Smyrna. Prof. Nebil Bilhan, Istanbul University, reported five cases in adults (20 to 42 years old). Three patients were from Istanbul, and two were from Bursa; four recovered, and one died of agranulocytosis. The late Dr. Osman Serefeddin Çelik, Istanbul Charity Hospital (Topkapu), diagnosed the disease in three adults. Associate Professor Celal Ertug, Ankara University, and Dr. Asil Mukbil Atakam, Koya, each reported one adult case. In 1945, Professor Çetingil reported a case in a man of 40; the patient was given ethylstibamine therapy and recovered.

The kala-azar seen in Turkey resembles the Mediterranean type, it occurs mostly in children. Almost all patients contracted the disease in Istanbul or its environs, or on the Marmara, the Aegean or the Mediterranean seacoast. Kala-azar contracted on the Black seacoast has not yet been reported. Two patients were natives of Rize, on the Black seacoast, but had evidently contracted the disease in Istanbul. There have been no hospital cases of kala-azar in Central Anatolia reported in Turkish medical literature. Kala-azar has been added to the list of insect-borne diseases occurring in Turkey. During the summer and autumn, the phlebotomus is found almost everywhere in Turkey—mostly P. papatasii, but P. major, sergenti, chinesis and minutus are also encountered. As the symptoms of kala-azar closely resemble those of malarial fever, Leishmania organisms are looked for in all patients in whom a diagnosis of chronic malaria has not been absolutely confirmed. All hospitals in urban and rural communities provide free examination and treatment. Why kala-azar in Turkey is sporadic and never epidemic has not yet been ascertained.

Hydatid Cyst in the Parametrium.—Dr. Emir Necip Atakam, chief of the Istanbul Şişli Hospital gynecological department, reported a case of a single, primary hydatid cyst in the parametrium. The patient, a 19 year old married woman, had a normal delivery at 17. A year later, she had an abortion, followed by an elevation of temperature for six days. From then on menstruation was painful, and a gradually increasing swelling with pain toward the anus developed in the left inguinal region. The swelling was soft on palpation and sensitive on pressure; the liver and spleen were not palpable. There was no sensitiveness in other parts of the abdomen. Pelvic examination revealed an intraligamentary cyst, which was tight and hard and the size of a large orange, the conical fluctuating end projecting into the vagina. The right inguinal region was normal; the Douglas pouch was closed. The red blood cell count was 3,340,000, the white blood cell count 8,400, and the hemoglobin value 72%. The differential study of the white cells showed 7% eosinophils; sedimentation and coagulation rates were normal. Weinberg and Casoni tests elicited positive reactions, and surgical intervention was decided on. The abdominal cavity revealed a cystic tumor the size of a child's head, and a clear fluid was removed by trocar. Through the widened opening, the germinative membrane was pulled out and cleared of all echinococci; the cavity was swabbed with iodine and closed by capitonnage. Recovery was uneventful. Most pelvic hydatid cysts are multiple, but in this case the lesion was single. Also, most Echinococcus granulosus tumors are secondary; in this case it was primary.

BRAZIL

Biopsy During Operation.—Dr. Ernani T. Torres, head of the department of pathology of the Rio de Janeiro Hospital dos Servidores, published a report on 1,000 successive biopsies performed during operation; 1,258 specimens were examined. In this series, the pathological and clinical diagnoses coincided in 890 cases (89%); in 109 cases (10.9%) the clinical diagnosis was changed by the result of the pathological examination performed during the operation, and in many instances the surgical operation was modified according to the results of biopsy. In only one case was a definite diagnosis not possible. The patient concerned had had jaundice for the previous seven months and, recently, loss of weight, abdominal pain, and dyspnea. There was rigidity of the abdomen and evident guarding over the right hypochondrium. The clinical diagnosis was obstructive jaundice, rupture, or perforation of the biliary ducts. An exploratory laparotomy was performed, with excision of Vater's papilla. The biopsy performed during surgery demonstrated a chronic inflammatory process, but serial sections made later for more complete examination demonstrated the presence of a grade 2 adenocarcinoma (Broders), involved in abundant fibroblastic proliferation.

The pathological examination was indispensable for the exact diagnosis of the diseases of the breast in 25.6%, of the stomach in 12.6%, of the female genitalia in 9.1%, of the bones in 83.3%, of the thyroid in 9.3%, and of the mouth, tongue, throat, larynx, and frontal sinuses in 43.9%. The clinical and the pathological diagnoses coincided in the diseases of the breasts in 74.4%, of the stomach in 87.4%, of the female genitalia in 90.8%, of the bones in 16.7%, of the thyroid in 90.7%, and of the mouth, tongue, throat, larynx, and frontal sinuses in 56.1%.

Roentgenological Changes in Small Intestine in Infectious and Parasitic Diseases.—Drs. J. Rodrigues da Silva and Helio Morais, of the Rio de Janeiro Hospital dos Servidores, reported the results of their x-ray study of the small intestine in 95 hospital cases, in 74 of which there were symptoms caused, at least partially, by the following agents, alone or associated: Schistosoma mansoni (38 cases), Ascaris lumbricoides (30 cases), Trichuris trichiura (13 cases), salmonellae (10 cases), Endameba histolytica (8 cases), shigellae (6 cases), and Strongyloides stercoralis (4 cases). The rest of the patients (21) had no evidence of any parasitic or infectious disease, but their nutritional condition did not differ from that of the other patients, except for some digestive troubles that led to the diagnosis of irritable colon. The x-ray findings in the small intestine of patients having the aforementioned parasitic and infectious diseases were more frequently represented by changes in motility and tonus; hyperperistalsis and hypertonia were the most frequent findings; hypotonia and retardation of the transit were rare. In a few cases meteorism and mucus were present, but in only one case a slight abnormality of the mucosal pattern was reported in the jejunum. These roentgen changes were not characteristic with respect to each cause, contrary to what might be expected because of pathogenic differences. The only notable fact was a greater frequency of hypertonicity in patients with mansonic schistosomiasis. Silva and Morais could not confirm the presence of indisputably organic lesions already described by a few authors in cases of chronic amebiasis and shigelloses, nor could they find the changes that form the full picture of the so-called nutritional disturbances pointed out by some authors of works on mansonic schistosomiasis, intestinal parasites, shigelloses, and chronic salmonelloses.

The authors believe that it is not yet possible to interpret the exact mechanism of the roentgen changes found in the course of these parasitic and infectious diseases. They point out that the absence of roentgen changes with respect to the functions of the muscularis mucosae adds to the improbability of local factors as causative since such factors affect the muscularis mucosae more frequently than the muscularis propria. The occurrence of these same roentgen changes in patients with an irritable colon, without parasitic-infectious etiology, points to systemic factors as causative.

COLOMBIA

French Medical Mission.—Drs. Paul Harvier, clinical internist; Joseph Logre, psychiatrist; Marc Richard Klein, neurosurgeon; Antoine Remond, electroencephalographist, and Guillaume Valetta, pharmacologist, were recently invited by the members of the National University of Colombia for a scientific "good will" trip to Colombia. The aforementioned invited members of the French medical mission arrived in Bogotá on March 27, 1951. They conducted an interesting scientific and social program for two weeks in Bogotá and one week each in Medellin and Cartagena. The program included lectures in the faculties of medicine of the aforementioned cities and clinical lessons on experimental and surgical demonstrations in hospitals. Many social festivities were organized to honor the French physicians. The main purpose of the mission was to strengthen the cultural and scientific relations between members of the French and Colombian medical profession.

Phosphoric Esters of Thiamine in Diabetes Mellitus.—The clinical and experimental results of administration of phosphoric esters of thiamine obtained by Drs. Gonzalo Montes Duque and Julio Cárdenas Araque were discussed in a previous foreign letter from Colombia (*J. A. M. A.* **144:**1394 [Dec. 16] 1950). Results of this treatment in four patients with diabetes mellitus are reported in *Revista de la Sanidad Militar de Colombia* (Nos. 3 and 4, Dec. 1950). Two were treated with phosphoric esters of thiamine (cocarboxylase) and the other two with the orthophosphate of thiamine. Both substances were given orally in daily doses varying from 400 mg. to 1 gm. The patients were observed for periods varying from four days to one and one-half months. In all patients glycosuria disappeared and the blood sugar returned to normal while the patients were taking the drugs, even if they did not have the proper diet. The authors believe that the phosphoric esters of thiamine aid in the phosphorilization of dextrose in the body, facilitating the effects of hexokinase. It is also possible that the aforementioned substances facilitate the passage of dextrose through the cellular membranes to be used by the cells. In an introductory note the authors state that they were informed by the workers of a well-known American laboratory that they were unable to reproduce the experimental results obtained in rabbits in the laboratory of the faculty of medicine of Bogotá.

CORRESPONDENCE

NATIONAL FOUNDATION FOR INFANTILE PARALYSIS

To the Editor:—On behalf of the National Foundation for Infantile Paralysis and the thousands of American families who support its fight against infantile paralysis, I want to thank the fine men and women in the various branches of the medical profession who served poliomyelitis patients so willingly and competently during 1950, the second highest year of polio incidence in the history of the United States.

The doctors, nurses, physical therapists, nonprofessional and volunteer hospital personnel—all who make up the polio medical team—deserve our warm tribute. They are the ones, in the final analysis, who can give the poliomyelitis patient the thing he seeks: an opportunity to return to his family and to his community a whole person. Through his acute illness and through the long re-education and rehabilitation period needed by the severely handicapped, the polio patient needs not only the skill of each member of the medical team, but also their personal interest, the strength of their encouragement, the understanding of his own problem which only they can give him. Unstintingly they have given this service to the poliomyelitis patient.

The American people who support the National Foundation make possible its program of providing financial aid to needy polio patients and of supplementing existing polio facilities and personnel in communities hit by epidemic. We can be successful, however, only in proportion to the cooperation we receive from hospitals and the many and varied personnel needed to serve the polio patient. Without their help we would not have been able to meet the heavy onslaught of polio in these past few years.

The National Foundation for Infantile Paralysis is deeply grateful to all those whose services helped to bring to each poliomyelitis patient his full chance for recovery.

Basil O'Connor, *President,*
The National Foundation for Infantile Paralysis, Inc.,
120 Broadway, New York 5.

MISMATCHED BLOOD TRANSFUSION

To the Editor:—In reference to the article "Successful Treatment of Mismatched Blood Transfusion," by Varney et al. (*J. A. M. A.* **145:**978 [March 31] 1951), I believe certain facts regarding hemolytic transfusion reactions should be noted. I do not believe alkalinization of the urine is of any use in the treatment of anuria due to so-called lower nephron nephrosis, nor do I believe precipitation of acid hematin is an important factor in the causation of this condition. It has been shown that overburdening of the patient with intravenous fluids, in the amount indicated in the case report, is a most frequent cause of cardiac failure, pulmonary edema, and death.

The important steps in the management of hemolytic transfusion reactions are first, relief of anoxemia by raising of the hemoglobin to normal values with transfusion of compatible whole blood or packed red blood cells; second, restriction of fluids to approximately 1,000 cc. per 24 hr. above the output; third, maintenance of electrolyte balance, the mode to be determined by carbon dioxide and serum potassium levels and electrocardiograms.

In the case reported, there was only transient oliguria with the development of little, if any, kidney damage. This, rather than the therapy used, is the explanation of the uneventful recovery.

Since the use of transfusion today is so routine, hemolytic transfusion reactions will be seen despite all precautions. Management of these reactions according to the method described in the article in question can lead only to disaster in most cases.

Leslie Hughes Tisdall, M.D.,
615 Third St., Brooklyn 15.

BUREAU OF LEGAL MEDICINE AND LEGISLATION

MEDICOLEGAL ABSTRACTS

Workmen's Compensation Acts: Employee's Right to Change Physician.—The claimant filed a proceeding to recover compensation payments for temporary total disability resulting from an industrial accident and for necessary medical and surgical expenses. From a finding in claimant's favor by the industrial commission, the employer appealed to the Supreme Court of Minnesota.

In May, 1945, while employed by the Oliver Iron Mining Company, the claimant was engaged in pulling a heavy piece of timber with a "come-along," a device with a wooden handle on each end and a pair of tongs in the center, used for dragging timber along the ground. While thus engaged, the "come-along" slipped out from the timber, and the employe fell backwards five or six feet onto an uneven pile of logs, striking his back and shoulder on the sharp edges thereof. He testified that as the result of the fall his back immediately commenced to pain all over and hurt him so much that he thought it was broken; that he lay on the timber at least 10 minutes before he could move and then got up and resumed work, but that the pain in his back continued thereafter. On the same date he reported the accident to his foreman and at the latter's direction, on the following day, the claimant went to the Shipman Hospital for examination and treatment by the company doctors. X-rays were taken, and one of the doctors, after feeling claimant's back and examining the x-ray, informed the claimant that the extent of his injuries appeared to be a bruise on his back some place around the ribs; and that the x-ray did not disclose anything further. During the next two years the claimant was in and out of the hospital five or six times, as the pain disappeared and recurred, but nothing specific was done for him. In March, 1947, still suffering pains in the lower part of his back, the claimant called upon a doctor of his own choice, Omer E. Snyker. Dr. Snyker immediately was impressed with the possibility of a spinal injury. He strapped the claimant's back and advised him of its proper use in working and lifting. The doctor testified that his later physical findings, which disclosed radiation of pain in employee's legs and nerve muscles, confirmed his earlier diagnosis of a possible spinal injury. He asked the claimant if he had sustained any accident, and was told of the fall which occurred on May 25, 1945. Dr. Snyker then recommended a spinogram x-ray and referred the claimant to Dr. Smith of St. Paul for such purpose. Before acting on his advice, however, the claimant endeavored to obtain relief from a local chiropractor. Unsuccessful in this, he returned to Dr. Snyker and in August, 1948, journeyed to St. Paul for the spinogram x-ray recommended by the latter. This was taken at Miller Hospital under the direction of Dr. Smith, who also made a physical examination of the claimant. Based on the spinogram and the physical examination, Dr. Smith concluded that the claimant was suffering from a herniated intravertebral disk pressing directly on the corresponding lumbar nerve and that the disk had already ruptured. On Aug. 27, 1948, Dr. Smith performed an operation on the claimant's back, removing segments of the perforated disk therefrom, following which claimant made an uneventful recovery. Dr. Smith testified that the fall which the claimant sustained in May, 1945, was, in his opinion, the cause of the ruptured disk for which he was treated and operated upon. Dr. Snyker testified likewise. Dr. Smith gave further testimony that many people experience disk injuries of this kind from a fall such as was disclosed by claimant; that ordinary X-rays are usually negative insofar as this type of injury is concerned, which was the reason for requiring a spinogram x-ray; that when the pain is due to a disk it may be temporarily relieved when the disk slips back into normal condition; that when the disk cannot resume its normal position the pain becomes constant; and that sometimes it is a matter of months before the disk gets out of position far enough to cause pressure sufficient to extend the pain to the leg of the injured person.

We believe, said the Supreme Court, that the evidence is amply sufficient to sustain the findings of the industrial commission that the claimant's injuries were due to the fall. It is the employer's contention, however, that the claimant was not authorized to change physicians without the consent of the industrial commission, and that hence it is not liable for the additional expenses thus incurred by the employee in effecting his cure.

The Workmen's Compensation Act provides: "The employer shall furnish such medical, surgical, and hospital treatment, . . . as may reasonably be required at the time of the injury, and during the disability, to cure and relieve from the effects of the injury. In case of his inability or refusal seasonably to do so the employer shall be liable for the reasonable expense incurred by or on behalf of the employee in providing the same. . . . The commission may at any time, upon the request of an employee or employer, order a change of physicians and designate a physician suggested by the injured employee or by the commission itself, and in such case the expense thereof shall be borne by the employer. . . ."

The statute thus indicates two separate situations in which a change of physicians furnished an employee under the act is permitted at the expense of the employer, pointed out the Supreme Court. In the first situation, the court continued, the statute does not specify that as a prerequisite to such a change an order therefore be procured from the commission. The inability or refusal of an employer or his physician to furnish the needed medical, surgical, or hospital treatment certainly would justify an employee in making an immediate change without jeopardizing his health or condition by even the slight delay involved in awaiting authorization therefor by the commission. In the second situation the statute contemplates that at the request of either employer or employee a change of physicians may be authorized by the commission in its discretion, even though the physicians furnished by the employer are providing proper medical treatment, since other factors, such as the convenience of parties, the location of required hospital facilities or medical equipment, the need for further specialized treatment, or many like considerations, may be deemed sufficient to authorize a change.

In a prior Minnesota case it was held, where physicians furnished by the employer for a period of more than 16 months "had fumbled and delayed the discovery of relator's real needs and requirements and had failed to furnish the professional aid really owed to realtor," that "the statutory equivalent of 'inability or refusal seasonably' to furnish and provide that which the statute requires" had been established. Based thereon the Supreme Court upheld the employe's right to change physicians at his employer's expense, even though the commission had failed to grant or act upon his request for such procedure.

In the present case, said the Supreme Court, the evidence establishing inability or refusal to furnish proper diagnosis and adequate treatment of the claimant's disability is even more substantial than in the prior case. Here, notwithstanding repeated visits by the claimant to his employer's physicians for a period of over 21 months, no proper diagnosis of his disability had been made and no adequate medical or surgical treatment provided therefor. The evidence established that a spinogram x-ray is required for proper diagnosis of a disk rupture, but no spinogram was suggested by employer's physicians. As far as the record indicates, there was never even a suspicion on the part of any of them that a disk rupture was the basis of claimant's disability. Dr. Snyker, on the other hand, on claimant's first call, suspected a spinal injury, while the diagnosis subsequently made by Dr. Smith after the spinogram x-ray quickly established claimant's need for immediate surgery, which was furnished and which shortly effected his cure.

We hold, the court concluded, that the evidence outlined was sufficient to establish the inability and refusal of employer's physicians to furnish the required treatment and to justify the claimant in seeking further medical attention from physicians and surgeons of his own choice; and that under the circumstances an order of the commission authorizing the change was not required. Accordingly the judgment in favor of the claimant was affirmed.—*Mattila v. Oliver Mining Co., 46 N.W. (2d) 82 (Minnesota 1951).*

Irradiation Therapy of Leukemias.—Osgood believes that the use of massive doses of ionizing radiation in the treatment of leukemia is irrational, since such doses do not kill all leukemic cells and do have many undesirable side effects. He favors the use of multiple small doses at regular intervals to inhibit leukemic cell growth without discomfort to the patient, and he fells that every leukemic cell must be irradiated at once. These concepts led to the development of the technique of "titrated," regularly spaced, total body irradiation by roentgen spray or radioactive phosphorous therapy. The roentgen therapy is given in the following manner: 200 to 400 kv.; no cone, 0.5 mm. Cu and 1 mm. Al filtration; 80-100 cm. target skin distance; two ports for adults. The initial dose is 10 to 20 r. The maximum subsequent dose is 25 r given at one to two week intervals for about six weeks. Subsequently 10 r per month is given for maintenance of control. Dosage is kept, if possible, below the level that produces anemia, bleeding, weight loss or any interference with the patient's daily routine. When P^{32} is used, the initial dose is 20 to 40 μc. per kilogram of body weight and subsequent doses and time intervals, as with roentgen therapy, are determined by the patient's response, which may vary greatly. Since the half life of P^{32} is eight days, dosage effects are cumulative if the interval is much less than six weeks. In the author's series of 58 patients (20 with chronic granulocytic leukemia and 38 with chronic lymphocytic leukemia) treated between 1941 and 1949 there are 32 still living. The mean duration of life from the onset of the disease is 3.6 years for the total series. While this is not significantly greater than the estimated 3.5 years natural life expectancy of patients with chronic leukemia, it is noteworthly that over 80 per cent of the total 208 years of leukemic life in this series was spent in essentially normal living.

Antibiotic Synergism and Antagonism.—Experiments in vitro with both gram-positive (Streptococcus) and gram-negative (Klebsiella) organisms and in vivo with streptococci in mice have demonstrated that chloramphenicol interferes with the bactericidal or therapeutic effect of penicillin. The antagonism extends over wide ranges of concentrations of the drugs, but these ranges are determined by the degree of antibacterial activity of each drug; for example, low, nonbacteriostatic concentrations of chloramphenicol do not inhibit the action of penicillin against Str. pyogenes, whereas high bacteriostatic concentrations of chloramphenicol do not interfere with the weaker action of penicillin on K. pneumoniae. These findings suggest that the two drugs do not interact in a chemical or physical way. This impression is confirmed by the observation that the antagonism occurs only if chloramphenicol is given prior to or simultaneously with penicillin. Apparently, chloramphenicol interferes only with the early bactericidal effect of penicillin, probably by modifying the characteristics of the bacterial population so as to make it less susceptible to penicillin. Drugs synergistic with penicillin, e. g., streptomycin or bacitracin, can overcome the antagonism between chloramphenicol and penicillin.

Intermittent Peritoneal Lavage.—Grollman and co-workers state that intermittent peritoneal lavage is superior to other artificial methods for removing excess waste products from the blood or adjusting the water, electrolyte, and acid base balance of the body. It is superior to the artificial kidney or exchange transfusions in that it requires no complex apparatus, cannulation of blood vessels, or large supplies of blood and it is less expensive and less dangerous. It also avoids the complex apparatus, multiple incisions, and constant attention required for constant peritoneal perfusion, and it may prove more effective. Intermittent peritoneal lavage has prolonged the life of nephrectomized dogs in good condition for 30 to 69 days, several times longer than by any other method, and has produced striking clinical improvement in three of five uremic patients. In man 2 or 3 liters of a special perfusing fluid are introduced into the peritoneal cavity through an ordinary paracentesis trocbar or small plastic tube. The fluid is left in the peritoneum for two hours, then siphoned off through the same tube. This is repeated every two hours. Alteration of the composition and tonicity of the perfusing fluid alters the composition of the blood and the volume of the interstitial fluid. The addition of 25,000 units of sodium penicillin and 25 mg. of streptomycin to each liter of solution and the use of sterile technique prevents the development of peritonitis. In the authors' experiments there was no evidence of peritoneal irritation or decrease in the efficiency of the peritoneum as a semipermeable membrane many weeks after the procedure had been performed. The procedure may find application in conditions such as profound disturbances of water and electrolyte metabolism, pulmonary edema, and congestive failure not responding to usual therapeutic methods, and acute hypertensive encephalopathy.

---

The Association library lends periodicals to members of the Association and to individual subscribers in Continental United States and Canada for a period of five days. Three journals may be borrowed at a time. Periodicals are available from 1940 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied with stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted.

disease. The authors followed 390 patients for five to 10 years after this operation. The hearing of 70% of the patients showed significant, sustained improvement; 20% lost some of their initial gain but retained a usable level of hearing; 5% had no hearing improvement, and 5% were considered to have bony closures. The number of probable bony closures was reduced to 0.6% during the last two years by the use of most of the features of the "improved Northwestern University technique." Symptoms of inner ear disturbance suggesting labrynthine hydrops were noted in more than 10% of the patients postoperatively. Pregnancy following the fenestration operation did not seem to result in further cochlear nerve damage. Progressive cochlear nerve degeneration was noted much more frequently in ears not operated on than in ears operated on. The operation thus affords at least partial protection against future cochlear nerve degeneration. The mechanism of this protection is not known.

Posterior Colpotomy in Ectopic Pregnancy.—While in some patients a fairly definite diagnosis of ectopic pregnancy can be made from the history, physical examination, and laboratory observations, in most instances the presence of an ectopic pregnancy must be confirmed by surgical inspection of the site of pregnancy. Draa and Baum stress the value and safety of the posterior colpotomy incision. If insufficient endometrial scraping was obtained for diagnosis, the posterior cul de sac was opened and inspected for fresh or old blood. Then the tubes, ovaries, and uterus were inspected. If the ectopic pregnancy was an early one, it was usually removed. Occasionally, fibrinous adhesions would hold an early ectopic pregnancy against neighboring structures, but these often could be freed by gentle finger dissection. The diagnosis was established for 149 of the 224 cases of ectopic pregnancy by the use of the posterior colpotomy incision and in 77 of these the pregnancy could also be removed through the incision. Laparotomy was required 72 times after the posterior colpotomy incision, the ectopic pregnancies in this group being of longer duration. The posterior colpotomy incision will aid in diagnosis and prevent delay in treatment of extrauterine pregnancy and will also prevent unnecessary laparotomies. Although it is a simple, safe procedure, it has been used by few surgeons and has been condemned because of the danger of introducing infection into the peritoneal cavity. This has not been the experience of these authors.

Incidence of Ectopic Pregnancy.—In 19 hospitals within the population registration area of the city of Baltimore, the racial incidence of ectopic pregnancy in relation to total births during five years (1944-1948) was determined. The unreliability of individual hospital statistics was shown in variations of ratios of ectopic pregnancies to total births in white patients from 1: 111 to 1: 269 and in Negroes from 1: 31 to 1: 862. There was one ectopic pregnancy to 177 total births in white women, as compared to one ectopic pregnancy to 120 total births in Negro women. The mortality from ectopic pregnancy during the five year period was 0.7% for white patients and 3.9% for Negroes. In view of the high incidence of gonorrheal infection in Negro women, the conclusions would seem inescapable that the differential in racial incidence of ectopic pregnancy is attributable to a higher incidence of pelvic inflammatory disease in Negroes. If this is true, the more efficacious methods of treating gonorrheal infection now in widespread use may well lead to a reduction in the incidence of this frequent and grave complication of pregnancy.

Visual Problems of Supersonic Speeds.—Factors relating to the use of the eyes in the flying of aircraft at supersonic speeds are briefly outlined. The following problems are discussed: The optical effect of the shock wave and the effect of slanting surfaces on incident light; the effects of vibration on the eye and the effect of the delay in visual perception; the restricting visual effect of acceleration on the maneuverability of supersonic craft, and possible effects of temperature and high speed escapes on the eyes.

Chorionepithelioma of Choroid.—The occurrence of chorionepithelioma in the testicle is rare. Metastasis of such a tumor to the choroid is exceedingly rare. The case here presented concerns a man, aged 22, who, following removal of a testicle in which chorionepithelioma was found, received a course of irradiation to the groin. He was symptom free until almost one year later, when pain developed in the left upper quadrant of the abdomen. An exploratory operation revealed metastatic nodules in the liver. Dimness of vision developed 10 days later. The patient's course was downhill, and he died two months after development of eye symptoms. Histological studies during necropsy corroborated the diagnosis of chorionepithelioma in the eye metastatic from the testicle. Only four other cases of this type in males have been presented in the literature.

Pseudocysts of Pancreas.—Forty-four patients with pseudocyst of the pancreas were treated surgically at the Mayo Clinic during the years 1933 to 1947 inclusive. These cysts, which contain a semifluid material, are found adjacent to or occasionally within the pancreas. They may result from inflammation or trauma and do not have a lining epithelium, in contrast to a true retention type of cyst. Pseudocysts are one of the commonest types of cystic lesions of the pancreas. A patient with a cyst of this type has a history suggestive of recurring pancreatitis and has a rounded mass in the upper abdomen. The mass may change in size or at times disappear entirely. In this series incision and drainage was done in 19 of the 44 cases, incision and marsupialization in 12, complete excision in five, excision of cyst and partial pancreatectomy in three, partial removal of cyst in one, and no surgical treatment of cyst in four cases. At the Mayo Clinic it has been observed that unless unusually small, a pseudocyst does not lend itself to total excision, as it does not have the wall of a true cyst, is adherent to all surrounding structures, and may require an extensive operation for total extirpation. If complete removal were attempted in all cases, the operative mortality would be excessive. Internal drainage by anastomosis of the cyst to the stomach, gallbladder, or jejunum has been reported, but in most cases external drainage of adequate duration, preferably by marsupialization, if the cyst is large, appears to be the treatment of choice. Recurrence can generally be prevented. The danger of serious infection is minimal with irrigation and antibiotic therapy. Probably the main objection to this type of treatment is the prolonged care necessary while the cystic cavity is gradually being obliterated.

Cystadenoma of Pancreas.—A case is reported in which a benign cystadenoma of the pancreas was completely extirpated, and 56 cases collected from the literature are reviewed. Little is known of the etiology of pancreatic cystadenoma, and it occurs rarely. Cystadenomas are rounded, neoplastic masses with a coarsely lobulated surface. They vary from the size of a cherry to tumors as large as a football. They usually have a semitranslucent, fibrouslike, tense capsule. On palpation, they exhibit a tense, hard, nodular consistency. Their gross appearance may be likened to a mass of glass marbles set in a dense, rubbery substance. Sectioning reveals that the cystadenoma is usually multilocular, whereas the pseudocyst, which is the commonest among the pancreatic cysts, is usually unilocular or bilocular. Cystadenoma is a benign tumor, but its histopathological differentiation from cystadenoma carcinoma and multilocular cysts may at times be difficult. Clinically, cystadenoma is characterized by an insidious, slow growth. Later, a palpable tumefaction, abdominal pain in the upper epigastrium, dyspeptic symptoms and weight loss appear. Roentgen examination (with use of lateral plate technique) has proved a most valuable adjunct in diagnosis. Eight of the 56 cases had associated diabetes mellitus. The ratio of females to males was 7: 1. Complete surgical extirpation is the method of choice in the opinion of most authorities. The surgical mortality is about 13.6%. A plea is made to surgeons to keep in mind routine examination of the pancreas by palpation in the course of operations on the gallbladder, common bile duct, stomach, and duodenum. This procedure will afford him the opportunity to recognize the normal feel of the pancreas and thereby insure the disclosure of pathological disorders that would otherwise remain hidden.

Adrenocorticotropic Hormone in Atopic Dermatitis.—The beneficial effects of pituitary adrenocorticotropic hormone (ACTH) in bronchial asthma, ragweed hay fever, and other allergic disturbances prompted a study of its effect in atopic dermatitis. Patients were selected on the basis of typical acute dermatitis that had failed to respond completely to specific allergic management. Aggravation of the dermatitis could be induced following the ingestion of one or more known allergenic foods. Three patients were hospitalized, and acute exacerbations of their dermatitis were induced by the ingestion of foods to which they were known to be sensitized. Although allergenic foods were continued in their diets, each showed rapid clearing of the lesions of atopic dermatitis during short courses of pituitary adrenocorticotropic hormone therapy. This degree of improvement lasted four or five days following the cessation of treatment with the hormone in two of the patients in whom allergenic foods were continued in the diet. Another patient was managed similarly, except that allergenic foods were withdrawn from the diet coincident with the cessation of hormone therapy; his clinical improvement lasted 10 days. The fourth patient, of whom relatively less was known from the standpoint of specific food allergy, was treated with pituitary adrenocorticotropic hormone for three weeks; during the latter part of this interval the dosage of the hormone was gradually reduced. Although his diet was constant, dermatitis recurred two days after the cessation of therapy, but the recurrence was less abrupt and pruritus was less severe during the first 10 days of gradually recurring eczema. Each patient had a recurrence of dermatitis following the cessation of hormone therapy, at least as severe and in some instances more acute than that present for several weeks prior to the institution of treatment. This degree of severity persisted from one to three weeks and then reverted to the previous status. In general, the results of treatment with pituitary adrenocorticotropic hormone in atopic dermatitis are not as good as in hay fever and bronchial asthma.

Effects of Ultrasonic Energy on Spinal Cord and Nerves.—The question of the effects of ultrasonic energy on the nervous system has arisen because this type of energy has been used for disorders, such as sciatica and lumbago, that involve the nervous system. Paralysis was observed in laboratory animals after single applications of ultrasonic energy to the midline of the back given in practically the same manner as the recommended therapeutic application in cases of lumbago and sciatica. In further experiments on dogs and rats, with use of a sonostat, which generates sound vibrations at a frequency of 800,000 cycles per second, it was found that ultrasonic energy had much greater destructive effect on the spinal cord than on the sciatic nerve. The theory that there is an effect of ultrasonic energy on nerve tissue other than its heat effect is supported by two findings: (1) the occurrence of marked destruction of the cord when temperatures recorded in the spinal canal were as low as 42 to 43 C. after application of ultrasonic energy and (2) the occurrence of much less regular myelin degeneration in sciatic nerves with action potential completely blocked by ultrasonic energy than in those with action potential similarly blocked by direct heating. Whether ultrasonic energy can be safely used for therapy cannot be determined from this study. Perhaps a safe procedure for the therapeutic application of ultrasonic energy can be determined by further studies, if the moving technique of application (or pulsed energy) and smaller doses are used.

17-Ketosteroid Deficiency and Male Hormone Therapy in Rheumatic Fever and Arthritis.—Dunn called attention to the role of endocrine deficiency and the value of endocrine therapy in arthritis as early as 1940. In 1950 he performed routine endocrine examination on 17 boys (6 to 14 years of age) who were receiving convalescent care for rheumatic disease and found that three-fourths of them showed signs of severe hypogonadism. A group of 17 adult males who had arthritis showed an 88% incidence of low 17-ketosteroid content in their urine. A group of 30 women with arthritis showed a 66% incidence of reduced 17-ketosteroid content in their urine. Of two male children with rheumatic fever and arthritis, one was given male hormone therapy, and his recovery was dramatic; in the control patient, the illness ran the usual course. Both had been given routine antirheumatic therapy in the form of antibiotics, ascorbic acid, and salicylates. The 17-ketosteroid deficiency seems to produce an inferior constitutional environment which permits the unknown etiologic factor of rheumatic fever to invade the impaired collagen tissue structures in the fibromuscular, articular, and para-articular structures. Therapy with 17-ketosteroids in the form of testosterone propionate and methyl testosterone is indicated in the treatment of rheumatic fever and arthritis whenever a 17-ketosteroid deficiency is apparent. Hypogonadal male children should receive male hormone therapy earlier and in larger dosage. There seems to be no contraindication to the use of male hormone therapy in females with rheumatic fever. The beneficial effects of cortisone and pituitary adrenocorticotropic hormone in rheumatic fever and rheumatoid arthritis illustrate the value of ketosteroid therapy in arthritis.

Folic Acid Antagonists in Leukemia.—Ten patients with acute leukemia were subjected to a therapeutic trial with two of the folic acid antagonists, namely, 4-aminopteroylglutamic acid (aminopterin) and amethopterin (4-amino-N^{10}-methyl folic acid). The daily dose of aminopterin varied from 0.5 to 2 mg. with a total dose of 6 to 11 mg. A daily dose of 5 mg. of amethopterin was given for six to 11 days. Results were satisfactory but temporary in three patients, fair in three, and poor in four. The drugs appeared to be most effective in subacute lymphocytic leukemia and ineffective in the acute fulminating type. They produce only temporary remissions and do not cure leukemia. Folic acid antagonists are toxic to the patient, and daily leukocyte counts, platelet counts, and frequent checks of the bleeding and clotting time are desirable. Manifestations of toxicity, such as stomatitis, bleeding from the bowel, and thrombopenia necessitated discontinuance of the folic acid antagonists in three patients.

Effects of Drugs in Producing Vasodilatation.—Several drugs were tested for their immediate vasodilating action following a single intravenous injection in 16 patients, including 11 with arteriosclerosis of the lower extremities, one with arteriosclerotic endarteritis obliterans of the upper extremities, and four with vasospastic disorders of the lower extremities. Fifteen of these patients were given 75 mg. of 2-benzyl-2-imidazoline hydrochloride (priscoline®), 11 received 500 mg. of tetraethylammonium (etamon®) chloride, six received ethyl alcohol, and six received ether, 25 cc. in one-half liter of a 5% dextrose or isotonic sodium chloride solution. The intravenous infusion of 5% ether solution had a minimal effect on digital cutaneous blood flow, as measured by determination of skin temperature. The intravenous 5% alcohol infusion produced vasodilatation in one patient with vasospastic disturbances of the lower extremities but produced no rise in skin temperature in four patients with arteriosclerotic peripheral vascular disease. The administration of intravenous tetraethylammonium appeared to have a weak effect on increased cutaneous blood flow, as measured by skin temperature determinations. The effect was minimal and inconstant. Results suggested that tetraethylammonium is not a sufficiently potent agent for use in estimation of the degree of vasoconstriction in peripheral vascular disorders. The single intravenous injection of priscoline® appeared to be effective in relieving the component of abnormal vasoconstriction associated with arteriosclerotic obliterative vascular disease and in relieving vasospastic disorders. It was the most consistent and most effective vasodilator of the several agents used in this study. The presence of arteriosclerosis in the extremities does not necessarily indicate arterial insufficiency, but if this insufficiency is demonstrated to be present, then the use of vasodilating agents may clearly indicate to what extent it is due to organic occlusive changes. In addition to the demonstration of arteriosclerosis, the absence of palpable pulsations and decreased oscillometric excursions may not indicate occlusive organic arterial disease alone but may reflect abnormal vasoconstriction in the presence of sclerotic vessels. If there is no surface temperature response to the intravenous administration of priscoline,® it is probable that the arterial insufficiency is due to organic occlusion of the vessels as a result of thrombosis or mechanical block. The drug is offered as a test agent to aid in separation of the element of vasoconstriction from the mechanical obliteration of the lumen.

Polymyxin B and Polymyxin E.—In vitro tests showed that both polymyxin B and polymyxin E had a pronounced effect against some of the gram-negative pathogenic bacteria, which did not respond well either clinically or in vitro to any of the other presently available drugs. Polymyxin B and polymyxin E were given a therapeutic trial in 36 patients, 30 infants and children, and six adults, 22 with urinary tract infections, one with infection of both the urinary tract and the blood stream, nine with gastrointestinal infections, two with pulmonary infections, one with chronic otitis media, and one with meningitis. The infants and children were given 0.8 mg. of the drug per kilogram of body weight every four hours. All the adults were given the maximum dose of 20 mg. every four hours intramuscularly. Results showed that infections that may not respond to other less toxic drugs or antibiotics and for which polymyxin may be useful are those due to Escherichia coli, Aerobacter aerogenes, Pseudomonas aeruginosa, Shigella and Hemophilus influenzae. Polymyxin B appeared to be less toxic than polymyxin D. The principal evidences of toxicity due to polymyxin D were renal; those due to polymyxin B and E were neurological and allergic. The neurotoxic signs included weakness, drowsiness, ataxia, numbness of fingers and feet, impaired position sense, transient blurring of vision with diplopia, and nystagmus. All of these were usually mild and transient. Other evidences of toxicity were intense itching, especially about the mouth and face, feeling of very tight skin about the face, chilly sensations, sweating, and urticarial and maculopapular rashes. The latter symptoms were much relieved by tripelennamine (pyribenzamine®) hydrochloride. Most patients complained of moderate to pronounced pain at the site of the injection. The evidences of toxicity were much less pronounced in infants and children than in adults. Polymyxin is the most effective drug against serious infections due to most strains of Ps. aeruginosa. The drug should be considered also in infections due to other sensitive gram-negative bacteria that are resistant to other less toxic agents.

Headache and Vertigo Associated with Hypoglycemic Tendency.—Headache, and to a lesser extent vertigo, are common symptoms of patients with spontaneous hypoglycemia. The case histories of 72 patients complaining of headache or vertigo and whose symptoms were relieved by high protein diet were reviewed. In all patients the symptoms were reproduced or aggravated during the five hour dextrose tolerance test, which, in most instances, gave a low curve, especially from the second through the fifth hour. In only 15 patients did the fifth hour level reach the fasting level, and in seven of these 15 the curve was flat. Symptoms were usually produced when the level dropped to 70 or less; in others, the rapidity of the fall of the sugar levels appeared to be the important factor. The headache experienced is visceral in character and is described as being dull and throbbing. It is often present at night and may be related to meals. Patients respond well to a diet high in protein and low in carbohydrates. Supplementary feedings may be necessary.

Penicillin Therapy in Syphilis of Central Nervous System.—Ten patients with neurosyphilis and one patient with tertiary syphilis of the skin were treated with penicillin according to the following schedule: from the first to the fifth day respectively, doses of 5,000, 10,000, 20,000, 50,000, and 100,000 units of penicillin were injected intramuscularly every three hours. From the fifth to the fourteenth day, patients received 100,000 units intramuscularly every three hours, and an additional 1,000,000 units of penicillin dissolved in 500 cc. of isotonic saline was administered daily intravenously. As controls, six nonsyphilitic patients were treated in a similar way. Eight of the 11 syphilitic patients had toxic reactions, all delayed in type. These reactions occurred on various days during the intravenous treatment. Symptoms were malaise, headache, nausea, chilly sensation, and temperature elevation. Two patients also had exacerbation of syphilitic symptoms. Two patients (one with pulmonary complications) succumbed after institution of the therapy. Three of the six control patients had systemic reactions: headache, malaise, chills, and fever. In all but one patient, the onset of the reaction followed intravenous injection of penicillin by one to three hours. In all patients, including controls, reactions occurred only after intravenous administration, but it is possible that the increasing intramuscular dosage that preceded it sensitized the patients and accentuated the reactions. Another possibility is that penicillin might have a direct neurotoxic effect, as suggested by the fact that delayed reactions occurred in the control group. However, exacerbation of specific syphilitic symptoms in four syphilitic patients suggests that another mechanism was operating, separately or in combination with the above. Severity of toxic reactions contraindicates the use of combined intramuscular and intravenous administration of penicillin in the schedule described, in treatment of neurosyphilis.

Medicine as Social Instrument: Public Health. H. Emerson.—p. 289.

Cardiovascular Manifestations in Acute Poliomyelitis.—The incidence and character of cardiovascular disturbances were studied in 428 patients with acute poliomyelitis. Since 50% of the patients were adults, it was possible to compare the relative frequency of disturbances in the heart and blood vessels of persons of all age groups. Abnormalities of the electrocardiogram, including high-peaked, notched T waves, increase in P-R and Q-T intervals, a $Q_3 T_3$ pattern, T wave inversions in leads other than 3, depression of the S-T segment, and a $Q_1 T_1$ pattern were observed. In every case, the normal electrocardiographic patterns reappeared as the patients recovered from the acute phase of poliomyelitis. Thirty patients, eight less than 16 years old and 22 aged over 16, had prolonged elevation of blood pressure during their illness. Its development in most cases was probably related to hypoxia. Return to the normotensive state could be produced by establishment of a clear airway, overcoming of respiratory failure by various mechanical means or administration of oxygen. Myocarditis developed oftener and was severer in older patients than in young patients. The mild form is probably hypoxic in origin, whereas the severe form may be due to invasion of the heart by the virus. Pulmonary edema was revealed by necropsy in four of 16 fatal cases of the bulbar forms of poliomyelitis. Careful management of fluid intake in patients with bulbar disease is necessary. Intravenous hydration is probably best avoided. In one case sterile verrucous endocarditis was revealed by necropsy. The authors' observations as well as others cited in the literature support the growing concept of poliomyelitis as a diffuse disease rather than one limited to the anterior horn cells of the spinal cord. That damage may be produced in structures outside the nervous system is strongly suggested by the observation of severe myocarditis. The problem of the cardiovascular disturbances in poliomyelitis needs further study.

Analgesic Effect of Dromoran® in Postoperative Pain.—The analgesic effect of dromoran® hydrobromide (3-hydroxy-N-methylmorphinan hydrobromide), a new synthetic morphine analogue, in postoperative pain was compared with that of morphine sulfate in 623 surgical patients. Dromoran® hydrobromide (5 mg.) and morphine sulfate (10 mg.) were administered subcutaneously to 311 and 312 patients respectively. The first postoperative dose of dromoran® gave complete relief in 66.5% of the patients as compared to 46.2% with morphine. Following a total of 1,336 injections of dromoran,® complete relief was obtained in 75% of the patients, the average total number of injections per patient being four. After a total of 1,097 injections of morphine, complete relief was obtained in 54.7% of patients, the average number of injections per patient being 3.4. The average duration of analgesia produced by 5 mg. of dromoran® was 6.1 hours as compared to 5.8 hours with 10 mg. of morphine. The incidence of nausea and emesis was less with dromoran® than with morphine.

Procaine Hydrochloride in Osteoarthritis.—Fourteen patients with osteoarthritis of one or both knees had unsatisfactory results from procaine hydrochloride administered intravenously, either because pain was not relieved or reappeared rapidly, or because of unpleasant toxic effects or mechanical difficulties. Following this, 10 cc. of 2.5 to 3% procaine hydrochloride were injected by intrasynovial route into the involved joint and the patients were followed for a period of four months to one year. All were improved, and some were completely relieved. One resumed his occupation as a track walker, covering several miles daily, and another resumed her trade of retail grocer, in which she spends long hours daily on her feet without pain. The results were so satisfactory that recently five patients who had not received procaine hydrochloride intravenously were so treated intrasynovially with equally gratifying results. This would negate the possible conclusion that this improvement was due to delayed action of previous intravenous administration of procaine hydrochloride.

Estradiol Pellet Implantation in Carcinoma of the Prostate.—Nine patients between the ages of 50 and 74 with prostatic carcinoma were treated by subcutaneous implantation of 50 mg. pellets of alpha-estradiol every three to four months. This type of administration was not associated with the undesirable gastrointestinal effects that orally administered estrogenic compounds often produce. Subcutaneous administration assures a constant source of supply, in contrast to oral administration, which may be interrupted by forgetfulness, indifference, or other factors. Results were eminently satisfactory. Relief from pain was prompt and in most cases complete. The patients were maintained in optimal state, free from pain, gastric distress, and breast hypertrophy. Progression of the prostatic tumor and of metastases was retarded. Cachexia of advanced carcinoma was frequently reversed, with substantial gains in weight, increase in strength, and return to gainful occupation. Two patients, who were first seen in advanced stages, died. It is suggested that a sustained high level of circulating estrogenic substance has been responsible for the pronounced efficiency of the alpha-estradiol pellets used in the authors' cases.

Rh Factor in Obstetrics. M. S. Sichel.—p. 181.

The Physiological Position for Delivery.—The conventional positions now generally in use in obstetrics are the modified lithotomy position, with the patient on her back, and to a lesser extent the Sims position, wherein the patient reclines on her side, the upper knee being drawn up to the abdomen. Most lecturers in obstetrics pass lightly over the so-called physiological position, which is the squatting position. Williams' textbook, describing the second stage of labor, says "the primipara, . . . if left to herself, will usually assume the crouching or squatting posture." Buxbaum, discussing delivery in ancient times, describes the squatting position. The author of this paper cites several considerations that suggest that the squat or crouch is the physiological position for delivery. He describes a mechanism whereby tentorial tears are caused in the lithotomy position, and he shows that the physiological position minimizes this danger. The author recommends a specially designed obstetric chair-table.

Decubitus Ulcers in Patients with Paraplegia.—This paper reviews the surgical treatment of 102 decubitus ulcers in patients with paraplegia. Experience with two groups of cases attested to the soundness of surgical technique, which includes the following steps: complete excision of the ulcer and regional scar tissue, excision of regional new bone formation together with the underlying bony prominence, rotation of a flap of muscle over the exposed bone, closure of the wound by the use of a flap of skin and fat rotated to the area of the decubitus (placed so that suture lines and resultant scars are not over the site of previous decubitus) and the use of a free graft of skin at the point from which the flap was elevated. Excision of the underlying bony prominence has been reflected in an increased percentage of success in the operative closure of these ulcers. In 56 operative closures previously reported, 71% were successful. In the series of 70 operations reported herein, 81.5% were successful. As patients advance from life in bed to wheel chair existence, an increase in the occurrence of decubitus ulcers over the ischial tuberosities is noted. In these cases excision of the underlying bony prominence effected a dramatic improvement in the results of operative treatment. When this step was not employed, healed wounds were maintained in only 47% of cases; when it was employed, healed wounds were maintained in 80% of cases. Extensive calcification of soft tissues in paraplegic patients indicates a poor prognosis.

SYMPOSIUM ON TREATMENT OF AMEBIASIS

*Results with Diodoquin and Carbarsone. H. C. Conn and P. W. Feldman.—p. 137.
Results with Aureomycin. D. J. Mendelson and R. D. Friedlander. —p. 141.
*Results with Bismuth Glycolylarsanilate. H. C. Conn.—p. 144.

Diiodohydroxyquinoline and Carbarsone in Amebiasis.—A single course of therapy with diiodohydroxyquinoline (diodoquin®) and carbarsone was given to 497 patients with amebiasis. The dosage of diiodohydroxyquinoline was 0.63 gm. three times daily for 20 days. For 10 days 0.25 gm. of carbarsone was given twice daily. Patients were followed up for four years, with one examination every two months for one year whenever possible and then two examinations yearly for three years. The only toxic effects noted after administration of diiodohydroxyquinoline were frequent mild diarrhea and pruritus ani. After treatment with carbarsone one patient reported a mild skin rash, which quickly cleared after administration of the drug was stopped. Treatment failed in 66 of the 497 patients (13.2%). The percentage gradually became less as more examinations were made, but there were still some positive stools even after five successive negative specimens. Thus relapses were discovered after one or more years of presumed cure. Failures may be extremely resistant to treatment with any drug. The terms "arrested" or "apparent cure" seem to be much more appropriate in relation to amebiasis than that of "cure." Long-term follow-up is essential to proper control of amebiasis, which is becoming increasingly prevalent in civilian contacts of war veterans. A standard ideal laboratory diagnostic method using polyvinyl alcohol fixative stain as a preservative for trophozoites of intestinal amebas is suggested.

Bismuth Glycolylarsanilate in Amebiasis.—Thirty-six patients with amebiasis were treated with bismuth glycolylarsanilate (*milibis*®). The recommended adult dose is 0.5 gm. three times daily for seven days. In the presence of diarrhea larger doses may be needed. None of the patients reported on by the author had acute diarrhea, and they received only the above dosage. Treatment failed in four of the 36 patients (11.1%). One of the patients in whom treatment failed had two negative stool examinations after a second course of the drug. No toxic manifestations occurred in the group treated. It is felt that amebiasis in the future should be treated with chloroquine phosphate (aralen®) for systemic action and with a drug such as bismuth glycolylarsanilate for lumenal action. Long-term observation is a necessity in the treatment of amebiasis. All the drugs in use are effective in some cases. A few patients will be extremely resistant to any therapy. Patience and persistence will almost invariably produce a good clinical result.

Propagation of Pathogenic Fungi in Yolk Sac.—The studies reviewed in this report began with an attempt to produce infection of the chorioallantois with Actinomyces bovis. The extra-embryonic membranes were found to be indifferently suited for this purpose. Chance inoculation of the yolk sac resulted in the abundant growth of A. bovis. This observation led to a more thorough investigation of the possibilities of this method of inoculation for the propagation of pathogenic fungi and the study of mycotic infections. Embryos of seven to nine days' incubation proved to be most suitable for this purpose and were used throughout. The micro-organisms were introduced into the yolk sac of living embryos through a small slit in the eggshell by means of a tuberculin syringe and 22 gage needle. The yolk sac of the developing chick embryo proved to be highly suitable for the propagation of the following pathogenic fungi: A. bovis, Nocardia asteroides, N. intracellularis, Sporotrichum schenkii, Histoplasma capsulatum, Cryptococcus neoformans, and Coccidioides immitis. This method promises to be of value for the experimental study of these and other mycotic infections.

Loss of Vaccination Protection Following Cortisone Treatment.—The studies reported in this paper demonstrated that treatment with cortisone overcame the beneficial effect of vaccination in mice infected with a highly virulent strain of Mycobacterium tuberculosis, human type, but did not significantly increase the deaths in nonvaccinated mice. Treatment with cortisone increased the susceptibility of mice to infection with M. tuberculosis of reduced virulence. It is pointed out that exacerbation of tuberculosis during the hyperadrenal state has been observed in man and experimental animals. The mechanisms by which cortisone enhances the infectious process in experimental tuberculosis have not yet been completely elucidated. The results of the present study suggest that one of the mechanisms by which cortisone may alter the course of this disease is by interference with the immune response. In rapidly progressive tuberculosis where the role of acquired immunity would be expected to be minimal, cortisone did not exert a significant effect on the course of the disease. However, when vaccinated animals were treated with cortisone, the prolonged survival conferred by vaccination was lost.

Viomycin: Absorption and Excretion.—Viomycin, which is a derivative of a species of Streptomyces, has been of interest because of an inhibitory effect on mycobacteria, including M. tuberculosis, and because of its ability to suppress tuberculosis in animals. Preliminary clinical studies with viomycin in tuberculous patients have been carried out. The present study concerns the absorption and excretion of viomycin following its intramuscular injection in human subjects. It was demonstrated that viomycin was rapidly absorbed and that high concentrations were achieved in the serum after intramuscular injection. This may bear only a loose relationship to the successful utilization of the drug in antimicrobial therapy. However, the serum concentrations of viomycin that were attained were well in excess of the minimal inhibitory concentrations of viomycin required in vitro to suppress strains of M. tuberculosis isolated from patients with active tuberculosis. The pattern of absorption and urinary excretion of viomycin was similar to that of streptomycin.

Resistance of Tubercle Bacilli to Streptomycin.—Investigators from several sections of the country participated in cooperative studies on streptomycin resistance of cultures of tubercle bacilli isolated at intervals during a period of one year from 157 patients who had been treated with streptomycin for 91 days. At the end of 53 weeks tubercle bacilli could not be cultured from the sputum of 40% of the patients but could be isolated from the sputum of 55%. The remaining 5% of the patients had died. The tubercle bacilli of approximately two-thirds of the patients who still had positive sputum at the end of 53 weeks were resistant to streptomycin. This resistance to streptomycin tends to persist after the cessation of treatment, although reversion to streptomycin sensitivity was observed in cultures isolated from approximately 18% of patients. In the majority of patients, the development of resistance of tubercle bacilli to streptomycin occurred during the administration of streptomycin. Of 18 patients who could not be included in the program because their initial cultures of tubercle bacilli were found to be resistant to streptomycin, five had previously received streptomycin therapy. The development of streptomycin-resistant organisms may influence the patient's chances of converting to negative cultures.

Cysticercus Bovis in Cattle and Beef Tapeworm in Man.—Griffiths reviews the incidence of infection of cattle in Great Britain with Cysticercus bovis, the larval stage of Taenia saginata, the human beef tapeworm, and records the incidence recently observed by himself at an abattoir in the Liverpool area. The data indicate that within recent years there has been a decided increase in the incidence of C. bovis infection in cattle in Great Britain. It is therefore of importance to consider whether the incidence of the adult T. saginata has increased in the human population. In Denmark T. saginata infection in the human population increased with a rising incidence of C. bovis in Danish cattle. In Great Britain there is unfortunately little information available on the incidence of the adult tapeworm. It is known that there is a higher incidence of infection in women than in men. One report suggests that housewives may acquire the infection when beef is available in the raw state, i. e., in the kitchen before it is cooked. They also make the interesting observation that the cyst readily adheres to the hands, so that, in the preparation of diseased meat, the cysticerci may become attached to the hands of the housewife and thence be ingested. This tendency of cysticerci to adhere to the skin surface—and indeed to any surface—was noted by the writer when carrying out routine identification examinations of specimens received in the laboratory.

*Pedicle Graft for Ulcers of Lower Extremities. R. Brummelkamp.—p. 391.

Grafting of Cultivated Embryonic Parathyroid Tissue in Postoperative Tetany.—The various possibilities of therapeutic grafting are discussed, but particular attention is given to "real grafts," those which survive and become an integral part of the organism. In grafting endocrine gland tissue the following requirements must be fulfilled: the fragments must be thin; bleeding must be absent; the diffusion possibilities must be good; the revascularization must be fast; individuality factors must be in agreement or absent, and the grafts must be bacteriologically sterile. The work of Bert is mentioned, who stressed the importance of using tissues from embryos, because they do not yet possess much individuality and have a high regenerative power. Moreover, according to the work of several other investigators, cultivation of the tissues in mediums prepared from the future host is of great importance for good transplantation results. The authors of this report, Kooreman and Gaillard, started in 1940 to transplant cultivated fetal human parathyroid tissue into the patients with postoperative or with idiopathic tetany. Within three hours after death, the thyroid glands from newborn babies who died in the obstetric clinic were removed and stored in 10% placental vein serum in Gey's balanced salt solution. The thyroid gland was studied under the dissecting microscope. In this way organs such as extra thyroid glands, lymph glands, thymus glands, and real parathyroid glands could be seen. Neither topographical relations nor crude morphological criteria were sufficient to permit differentiation of the real parathyroid glands; all organs were therefore cultivated until—after one or two days—histological control and the behavior of the explants was absolutely conclusive on this point. After describing the cultivation of the tissues and the technique of implantation, the authors present the histories of the 27 patients with postoperative tetany and two with spontaneous tetany into whom 42 parathyroid grafts were implanted. The results of "real grafts" can be evaluated only after at least a year, since temporary grafts can be active for six or eight months. It was possible to evaluate 21 patients. The possibility of obtaining a positive result decreased with increasing age. Between 16 and 26 years of age four out of five patients were cured (80%). Between 26 and 36 years of age three out of eight patients were cured (37.5%). None of the eight patients between 36 and 56 years of age were cured. Repeated transplants were sometimes necessary to obtain a positive result in the younger groups.

Pedicle Graft for Ulcers of Lower Extremities.—Ulcers located on the anterior or medial aspect of the distal part of the leg are often refractory to treatment. The edges soon adhere to the tibia and become completely rigid. As the bottom of the ulcer rests on the tibia, vascular supply from the depth is only minimal; this renders the granulation tissue atrophic and inadequate as a substratum for the epithelium. However, the connective tissue reacts to wound irritation, in the crater as well as in the immediate vicinity of the ulcer. It will eventually begin to shrivel, thus constricting the afferent vessels and giving rise to a callous, ischemic mass in and around the ulcer. Once the process has reached this stage, spontaneous healing can no longer be expected. Lasting cure can be attained only by removal of all callous tissue and filling of the defect with full thickness skin. Implanting of full thickness skin with a layer of fat on such a defect is possible only by means of a pedicle graft. Fortunately, this persistent form of ulcer is nearly always situated along the anterior or medial aspect of the distal part of the leg. It is therefore possible to place the affected leg in such a position that the wound lies adjacent to the calf of the healthy leg from which the flap is taken. The author describes a method of suspending the donor leg freely over the affected one. This method offered no difficulties of fixation or nursing. The five patients treated in this manner all showed a favorable result.

Constitution and Insulin Sensitivity.—In a study of 95 diabetic patients, 38 (eight men and 30 women) were found to have an unremarkable constitution in that no characteristic features common to the group could be observed. Thirty-seven (six men and 31 women) conformed to a definite constitutional type recognizable clinically, although all the stigmas were not present in each case. The latter group tended to be overweight, on the basis of a weight-height ratio of 2:1 as the standard of normality. One-fifth of the patients examined were intermediate in type and could not be classified. The mean insulin sensitivity of the patients with an unremarkable constitution was 0.78, and in those with a characteristic constitution it was 0.48. Partial cor-

---

An asterisk (*) before a title indicates that the article is abstracted. Single case reports and trials of new drugs are usually omitted.

relation coefficients for insulin sensitivity and obesity in the two types of diabetics did not enable the authors to define precisely the effect of weight on insulin sensitivity, but their clinical impression was that in most cases the actual sensitivity of a patient is a fundamental constitutional characteristic. Anthropometric measurements and somatotypings from 225 diabetics were analyzed by other workers who observed that two clearly different morphological types could be recognized. Although no insulin sensitivity tests were carried out by these workers and no somatotyping was done in the authors' 95 patients, the similarity between the observations in these two series of diabetic patients is stressed. There are two constitutional types of diabetic patients who differ in their reaction to insulin and in whom the etiology of the diabetic state is probably different.

Megaloblastic Anemia Treated with Penicillin.—A native African woman with megaloblastic macrocytic anemia was given 400,000 units of crystalline penicillin G daily for seven days. The reticulocyte level rose to 37%, and this was followed by a rise in the hemoglobin and red blood cells. No other treatment was given. The megaloblasts had disappeared from the marrow by the fifth day of treatment, and the giant stab cells had become much less numerous. The Price-Jones curve, which had originally shown anisocytosis and macrocytosis, reverted to the normal pattern. The response to penicillin in this patient in no way differed from that obtained in other patients with megaloblastic macrocytic anemias when treated with a potent liver extract, pteroylglutamic acid, vitamin B_{12}, or a yeast extract (marmite). It is suggested that the penicillin may have been effective by destroying an organism that was competing for some hemopoietic substance or it may have removed a hematopoietic antagonist. It may have even prevented the absorption of glutamic acid by competing organisms, which might thus have interfered with the synthesis of pteroylglutamic acid. Penicillin may have affected the metabolism and excretion of some essential amino acids. Any or all of these concepts might explain the response to penicillin.

Trial of a Cinchoninic Acid Derivative.—Twelve patients, nine adults and three children, four with rheumatic fever, two with polyarteritis nodosa, three with scleroderma and three with lupus erythematosus were treated with a cinchoninic acid derivative, 3-hydroxy-2-phenylcinchoninic acid. The dosage used was 20 mg. per kilogram of body weight by mouth daily, which in some instances was increased to 40 mg. Seven patients were treated for one week, the remaining five patients for two or three weeks. The drug was taken after breakfast in three divided doses at hourly intervals. Fever and acute arthritis were speedily relieved in the patients with rheumatic fever. Results in polyarteritis nodosa were equivocal. The most striking effects were obtained in the patients with scleroderma, a disease hitherto not responsive to any known treatment. Improvement occurred in all three patients, as shown microscopically by biopsy specimens obtained before and after treatment. The results have so far been maintained in one patient and were only temporary in the other two. Slight and inconstant improvement followed the administration of the 3-hydroxy-2-phenylcinchoninic acid in chronic lupus erythematosus but was not confirmed by microscopic examination. Toxic effects were infrequent and less severe than those that may follow the use of sodium salicylate and consisted in slight nausea, diarrhea, and, more rarely, vomiting.

Old and New Problems of Goiter. W. Eickhoff.—p. 171.
Traumatic Cushing's Disease. H. Robbers.—p. 175.

Surgical Treatment of Prolapsed Lumbar Intervertebral Disk.—Various forms of prolapsed lumbar intervertebral disk, ranging from simple degeneration or chondrosis of the disk with rupture of the annulus fibrosus to a "sequestrated prolapse" on the dorsal-paramedian surface of the completely ruptured disk, may be observed, but usually surgery is definitely indicated only in the latter form. Decompression of the nerve root is the first and foremost aim of surgical treatment. Not all the patients with a compressed nerve root and not every patient with protruded lumbar intervertebral disk should be operated on. Two hundred and ten patients operated on for prolapsed lumbar intervertebral disk were followed up by the author for more than one to four years. Complete disappearance of the sciatic pain and of the back pain and restoration of work capacity was obtained in 40% of the patients. Except for temporary insignificant back pain, the same good results were obtained in an additional 25%, so that satisfactory results were obtained in a total of 65% of the patients operated on. Thirty per cent of the patients were considerably improved, with 19% able to resume their former work, while 11% could only perform lighter work. Thus a total of 95% of the patients were operated on successfully. Five per cent of the patients operated on were therapeutic failures because of considerable back pain, which prevented them from resuming work. For the majority of them fusion operation seems advisable. An additional 5% of the patients operated on had recurrences; of these 12 patients, seven made a complete recovery after a second operation, and two with a mild recurrence made a spontaneous recovery. A review of 6,600 patients operated on, followed up, and cited in world literature revealed satisfactory results in 83 to 95% of the cases.

*Problem of Perineal Endometriosis. J. Dubas.—p. 115.

Perineal Endometriosis.—The woman whose case is reported had undergone episiotomy in the course of a delivery 3½ years before. The area healed, and two weeks later the uterus had to be evacuated manually because of hemorrhage. The episiotomy scar was then ruptured, and, after that, healing was slow. Subsequently there was intermittent pain in the scar and occasionally there was bleeding, but real symptoms did not develop until about three years after the episiotomy had been done. An indurated area developed and gradually increased in size. The growth was painful, and drops of blood were discharged from it during the second half of the menstrual cycle. It was excised, and histological examination disclosed changes typical of endometriosis. This case is noteworthy because perineal endometriosis is rare. If the implantation therapy of endometriosis is accepted this may seem surprising, in view of the high incidence of perineal tears and episiotomies. The author feels that this rarity can be explained by the fact that the decidua expelled during the postpartum period is not implantable and is not capable of further development. Only mucosa in the phase of hormonal regeneration is implantable. It is suggested that in the reported case implantation took place not immediately after delivery but at the time of the profuse hemorrhage and uterine evacuation two weeks after delivery. The author believes that apart from rare hematogenous cases, perineal endometriosis arises from mechanical implantation.

Invaginations of Ileal Termination: Roentgenologic Examination. M. Fèvre.—p. 5.
*Surgical Treatment of Portal Hypertension by Portacaval Shunts. J. Auvert.—p. 26.

Portacaval Anastomosis for Portal Hypertension.—Portal hypertension as it is encountered in Banti's syndrome or in certain cirrhoses can cause massive hematemesis. The demonstration of esophageal varices is a pathognomonic sign of this syndrome. In this report Auvert discusses the various aspects of the surgical treatment of portal hypertension. The operations employed are of two types: (1) splenectomy followed by implantation of the splenic into the renal vein after nephrectomy on the left side and (2) implantation of the portal vein into the inferior vena cava above the renal veins. At the time of operation it is important to determine whether there is intrahepatic portal obstruction due to cirrhosis or extrahepatic obstruction of the portal vein or its branches (splenic or mesenteric). Special attention is given to the initial abdominal exploration during which proof is established for portal hypertension. After the incision has been made (preferably a transverse, subumbilical one) the stomach, the spleen and its vessels, the porta hepatis, and the entire liver are subjected to visual and manual exploration, and this is followed by manometry at various points for verification of the existence of portal hypertension and its location. Manometric tests may be combined with intraoperative roentgenography of the portal vein with the aid of a contrast medium. Depending on the observations during these preliminary explorations, the surgeon can then enlarge the incision along the ninth rib either to the right side of the thorax for direct portacaval anastomosis or to the left half of the thorax for splenectomy and splenorenal anastomosis on the left side. Although the postoperative administration of heparin may seem desirable, it is often dangerous. Follow-up examinations show that only large anastomoses will prevent the recurrence of hematemesis.

Dyshidrosis Produced by Ultraviolet Radiation.—In a hot, wet environment general ultraviolet radiation in moderate erythemal doses produced, in seven persons acclimatized to heat but not to radiation, up to 60% diminution in sweating rate on the second or third day after exposure. After recovery from the disturbance of sweating caused by one exposure to radiation, a second exposure produced a further fall in sweating rate in the same persons. The wave lengths causing the reduction in sweating rate are probably present in natural sunlight.

Cause of Changes in Sweating Rate After Ultraviolet Radiation.—The vesicular rash found in many subjects after ultraviolet radiation provided evidence that blockage of sweat gland ducts was at least partly responsible for the diminished sweating that followed the radiation. Occlusion of a proportion of the sweat gland ducts in irradiated skin was confirmed histologically. Blockage of sweat gland ducts, however, appears not to be the sole factor responsible for the decreased sweating. Indirect evidence suggests that the secretion itself is reduced. It is suggested that the reduced sweat secretion is brought about by toxins that have diffused from the injured epidermis. Skin injury produced by allyl isothiocyanate (mustard oil) also caused a fall in sweating rate similar in extent and duration to that produced by ultraviolet radiation. The slight reduction of sweating rate caused by locally applied massive doses of histamine suggested that the above effect of ultraviolet radiation and allyl isothiocyanate was not mediated through the release of a histamine-like substance.

Myocardial Ischemia and Its Surgical Relief.—Although myocardial ischemia is often manifested by angina or coronary thrombosis, in many cases it is more insidious: there may be shortness of breath on exertion, a sense of oppression in the chest, or other sign of cardiac dysfunction, such as congestive failure, auricular fibrillation, or heart block. Since medical treatment is of little avail, various surgical treatments have been tried. These include (1) attempts to reduce the metabolic activity by reduction in thyroid activity, (2) interruption of nervous pathways, so that pain is eliminated, (3) stimulation of intercoronary compensating circulation by obstruction of the flow in the cardiac veins, and (4) operations to improve the vascularity of the heart muscle by the provision of extracardiac collateral vessels. Mason reviews observations on 30 patients subjected to the last type of operation during the past 14 years. In his earlier cases the original O'Shaughnessy anterolateral thoracotomy and transpleural exposure of the heart were used, and a pedicled graft of great omentum was brought up and applied to the heart. Later Beck's revised approach was used. With this the third, fourth, and fifth left costal cartilages are removed, the pericardium being opened extrapleurally and between the intercostal bundles. The parietal pericardium was abraded with Beck's raspatories and then it was smeared with paste made of a purified wheat gluten preparation (aleuronat) or asbestos powder was insufflated into the sac. If the condition of the patient permitted, the omentum was first brought up, spread over the heart surface, and tacked to the pericardium. For a time the author avoided suturing directly to the heart, but he now feels that this probably need not be feared. Eleven of the 30 patients did not survive the first month, three were not relieved of their angina, and 16 are thought to have benefited from grafting, but in six of the 16, the relief is problematical. It should be remembered, however, that nearly all these were rather hopeless cardiac cases. To restore only a third of such patients to full activity, even temporarily, as well as to relieve them of their painful disability seems to have been worth while. Experience and better facilities for anesthesia will probably improve the results.

Intravenous Iron for Anemia of Pregnancy.—Resistance to orally administered iron therapy is comparatively frequent in pregnant women with anemia, but in these resistant patients the intravenous method is often effective. Scott and Govan treated 150 anemic pregnant women with iron intravenously administered. On the first day the equivalent of 30 mg. of elemental iron is given, on the second day 60 mg., and on the third day 100 mg. Thereafter 100 mg. is given daily until the end of the first week. During the second week, 100 mg. is given every second day, so that by the end of this week 790 mg. of elemental iron has been given. In moderate cases the blood is then above the anemia level, and the patient may then be given iron by mouth if necessary. Patients with severe anemia may continue to receive iron intravenously, 100 mg. every second day, in subsequent weeks, or once a week, according to the severity of the anemia. If a single dose of elemental iron exceeds 100 mg., severe reactions tend to develop. Minor reactions, such as pain in the arm, common to many types of intravenous injection, occurred in about 20% of cases. During the antenatal period most of the patients responded immediately, and with the dosage used there was an average increase of 1.5 gm. of hemoglobin per 100 ml. in a week. About a third of the patients showed no response until the second week of treatment. This delay seemed to be related to the availability of protein. During the puerperium the average response to intravenous iron almost reached the calculated level of 4% increase in hemoglobin per 100 mg. of elemental iron administered. In a few cases this figure might be exceeded, probably owing to the hemoconcentration, which begins usually about the third day after delivery. However, some puerperal patients did not respond immediately. In five the cause was infection and cardiac failure. The rest had suffered severe shock at delivery. Intravenous iron therapy is useful in anemia in pregnancy, especially when quick therapy is needed.

*Subacute Bacterial Endocarditis: Clinical, Anatomic and Therapeutic Studies in Chile. A. Garretón Silva.—p. 411.

Subacute Bacterial Endocarditis.—During the last 25 years the author has studied 605 cases of subacute bacterial endocarditis. The clinical aspects, special characteristics of the disease in Chile, the relation of the disease to rheumatic fever or congenital abnormalities of the heart, the diagnosis, prognosis, and pathological anatomy are discussed in detail. Penicillin was given to 172 patients whose disease was of rheumatic origin. This was administered on a three hour schedule with an initial dose of 200,000 units and a total daily dose of 1,600,000 units. Treatment was continued until the erythrocyte sedimentation rate was normal. The total dose varied from 8,500,000 units to 270,000,000 units. There was no correlation between the results of the pretreatment blood cultures and the results of penicillin treatment. Complete clinical cure occurred in 74 cases (43%). The ultimate outcome of these patients varied as follows: (1) permanent and complete clinical cure, (2) occurrence of embolism shortly after occurrence of apparent clinical cure (three cases in the author's group), (3) recurrence of the disease and subsequent control by reestablishment of penicillin treatment (four cases in the author's group), (4) clinical cure of the bacterial process with persistence of cardiac insufficiency, and (5) paradoxical clinical cure with appearance of progressive cardiac insufficiency and fatal outcome. The paradoxical results are frequent in patients with aortic lesion. The treatment in the three cases of persistent ductus arteriosus consisted of a surgical operation in two cases (with one cure and one failure) and successful penicillin therapy in one.

*Possibility of Accelerating Reabsorption of Intrapleural Blood by Means of Diffusion Factor: Preliminary Report of Experimental Study. B. Amistani and A. Vangelista.—p. 1208.
Frequency of Appendectomy in Patients with Cholecystitis. R. Cattaneo and P. C. Feraboli.—p. 1217.
*Tuberculous Peritonitis with Pseudoappendicular Symptoms. A. Mazzi.—p. 1220.

Reabsorption of Intrapleural Blood by Hyaluronidase.—Young dogs and rabbits were given intrapleural injections of their own blood mixed with an equal quantity of normal sodium chloride solution. Some were given 10 cc. of this mixture, others 300 cc. The injection was given into the right pleura through a small intercostal wound. Half the animals in each large group also received an intrapleural injection of 250 viscosity units of hyaluronidase, whereas the control animals did not. Daily roentgen examination of the dogs showed reabsorption of the intrapleural blood mixture usually within the first 24 hours after the injection in those receiving hyaluronidase or, in a few animals, within the first three days, whereas the quantity of the intrapleural blood mixture remained unchanged for five days or more in the controls. The rabbits were killed 24 hours after administration of the injection, and the residual intrapleural liquid was measured. There was half the quantity of residual intrapleural blood in the animals that had hyaluronidase in comparison to that measured in the controls. The results indicate that hyaluronidase favors reabsorption of blood collected in the serous cavities. The authors therefore advise clinical administration of the substance in all cases in which blood is collected into the serous cavities as a result either of a surgical operation or of trauma.

Tuberculous Peritonitis with Pseudoappendical Symptoms.—According to Mazzi, the pathological lesion of tuberculous peritonitis with pseudoappendical symptoms consists of a form of latent miliary tuberculosis, which is limited to the peritoneum and the ileocecoperitoneal segment. The lesion is not macroscopically identifiable. The author observed 230 patients who had an appendectomy for either acute or chronic appendicitis. Macroscopic lesions of tuberculous peritonitis were not seen during the operation. However, tuberculous peritonitis developed within three months after operation in 85 patients (38.99%). Hereditary predisposition to tuberculosis, temporarily diminished organic resistance of the patient, and, probably, surgical trauma transform the disease from latent to active. The author points out the danger of appendectomy in these cases and advises a careful evaluation of the clinical symptoms of appendicitis, either acute or chronic, in patients with previous symptoms of mild fever and pleuropulmonary or other diseases of tuberculous nature.

Significance of Medicometeorological Observations in Diseases of Nursing Infants. F. Trendtel and Helbig.—p. 317.

Selective Angiography of Pulmonary Vessels.—A preliminary report is presented on 300 selective angiograms of pulmonary vessels. Five to 12 cc. of 80% solution of methyl glucamine salt of 3,5-diiodo-4-pyridone-N-acetic acid (perabrodil-M 80%) were injected into the pulmonary artery. Serial roentgen ray pictures of the lung segment concerned were made after the injection of the contrast medium, so that all the phases of the circulation in the segment concerned could be demonstrated. The contrast medium should not be injected under pressure if one of the vessels has been obturated by the catheter. The patients were aware of the local anethesia in the region of the vena mediana cubiti, but they were not aware of the passage of the catheter through the right side of the heart into the pulmonary artery. By this technique arteriography does not entail opening or damaging of the arterial wall. Selective angiography of the pulmonary artery is indicated for the early diagnosis of bronchial carcinoma. It is emphasized that the angiogram of atelectasis is completely different from that of bronchial carcinoma. Early stiffness of portions of bronchi and of areas of pulmonary parenchyma due to flat growth of the neoplasm may be better demonstrated by angiography than by bronchography. Selective angiography of pulmonary vessels also proved valuable in cases of silicosis of second and third degree, in nearly all of which the venous reflex could be clearly demonstrated in the segment concerned. The method also revealed the length of time during which the contrast medium remained in the capillaries. Selective angiography of pulmonary vessels should not be used as a routine procedure, but it may be considered an adjunct to old proved methods, such as bronchoscopy, tomography, and bronchography.

BOOK REVIEWS

Neurology and Psychiatry in General Practice. Edited by Henry R. Viets, M.D. In collaboration with C. Charles Burlingame, M.D., Clarence B. Farrar, M.D., and Z. M. Lebensohn, M.D. Cloth. $3.50. Pp. 150. Grune & Stratton, Inc., 381 Fourth Ave., New York 16, 1950.

This small volume of sixteen chapters and 150 pages contains a wealth of material for the general practitioner which will aid him in the management of the neurological and psychiatric problems commonly encountered in his practice. The book is a summary of the discussions at the Clinical Session of the American Medical Association held in Washington, D. C., in the winter of 1949. The topics and the discussants were selected by the late Dr. C. Charles Burlingame, and the manuscripts were edited in a form suitable for the volume by Dr. Henry R. Viets, in collaboration with Drs. Burlingame, Clarence B. Farrar, and Z. M. Lebensohn. The choice of topics was excellent, and the leading authorities in the various fields have given a brief but lucid summary of the management of patients with the various disorders considered. Among the neurological conditions discussed are convulsive disorders of childhood and adult life, the Parkinsonian syndrome, neurosyphilis, and headache. Emphasis is placed on the medical therapy and general management of these conditions by the practitioner.

In the psychiatric section the physician is given information that will help him to decide which patients he can adequately care for and which ones should be referred to the psychiatrist for more intensive therapy. There are also chapters to orient the physician in regard to the value and limitations of electroconvulsive therapy and psychosurgery.

The book is well printed, and there is an adequate index. There are no illustrations, because the nature of the material presented did not require their use. The material presented in all the chapters is concise and relevant, and the volume should be of great value to the general practitioner.

Medical Psychology: A Basis for Psychiatry and Clinical Psychology. By G. K. Yacorzynski, Ph.D., Associate Professor of Nervous and Mental Diseases, Northwestern University Medical School, Chicago. Cloth. $6. Pp. 535, with 68 illustrations. The Ronald Press Co., 15 E. 26th St., New York 10, 1951.

This book has been prepared primarily as a textbook based on a theoretical-experimental approach. It is intended for use as a first year course in psychiatry. The author has presented only those theoretical constructs that have the widest acceptance and has endeavored to provide the experimental and clinical evidence from which they are derived. An attempt has been made to integrate the concepts of the behaviorist, Gestalt, and Freudian schools with the stated purpose of providing an integrated orientation for the student without the bias of any particular school.

The comprehensive coverage of the text makes it of value as a source background for psychiatrists, internists, sociologists, and other persons concerned with the problems of human behavior.

Medical Treatment in Obstetrics & Gynecology. By C. Frederic Fluhmann, B.A., M.D., C.M., Clinical Professor of Obstetrics and Gynecology, Stanford University School of Medicine, San Francisco, California. Cloth. $3. Pp. 157, with 27 illustrations. Williams & Wilkins Company, Mount Royal and Guilford Aves., Baltimore 2, 1951

This small volume will find a ready demand among busy physicians. Dr. Fluhmann has assembled a quick and authoritative answer to questions which perplex many physicians in attempting to use the recently developed medications in this field. The preparations available in female endocrinology have confusing names and dosages, but with this ready reference you can write a prescription that may even satisfy your pharmacist. This is a clear, concise book on materia medica for the obstetrician and gynecologist.

Surgical Forum: Proceedings of the Forum Sessions Thirty-Sixth Clinical Congress of the American College of Surgeons, Boston, Massachusetts, October, 1950. Surgical Forum Committee: Owen H. Wangensteen, M.D., F.A.C.S., Chairman, and others. Cloth. $10. Pp. 665, with 260 illustrations. W. B. Saunders Company, 218 W. Washington Sq., Philadelphia 5; 7 Grape St., Shaftesbury Ave., London, W.C.2, 1951.

This attractively printed volume represents a definite innovation in surgical literature. The Forum on Fundamental Surgical Problems was established in 1941 as a permanent feature of the clinical congresses of the American College of Surgeons. The forum was created to give an opportunity to the younger men engaged in research on surgical problems to present their work before the older members of the profession. The papers represent what is best in the field of surgical research. The length of an individual paper was limited to 3,000 words. The present volume consists of reports on original research dealing with practically every aspect of modern surgery. In addition to the regular papers, each subdivision contains a number of abstracts. These are brief reports by authors who for one reason or another could not complete their papers. The publication of this type of literature has two advantages: it gives the younger men an opportunity to present their research, and it stimulates the older men preoccupied with practical clinical work. The volume is well illustrated.

Studies in Pathology Presented to Peter MacCallum. Edited by E. S. J. King, T. E. Lowe and L. B. Cox. Cloth. $7; 35s. Pp. 350, with 48 illustrations. Melbourne University Press, Carlton, N. 3, Victoria; Cambridge University Press, 51 Madison Ave., New York 10; Bentley House, 200 Euston Rd., London, N.W.1, 1950.

This book presents a series of papers in the field of pathology which were written by students and associates of Peter MacCallum, pathologist, of Melbourne, Australia, on the occasion of his sixty-fifth birthday. The papers cover various aspects of morphologic pathology, but many of them are also of interest to the clinician and concern broad aspects of biology. Special reference should be made among the 23 papers to "The Contribution of Pathology to Biology" by King, "Metaplasia" by Willis, "Normal and Pathologic Patterns in the Liver" by Cameron, and "Vascularization and Hemorrhage in the Arterial Wall" by Wartman. The last two authors were associated with Peter MacCallum only a very short time, whereas most of the others have been his students. The papers, as well as the large number of excellent illustrations, make worthwhile reading and give information not necessarily available elsewhere.

History of the New England Female Medical College, 1848-1874. By Frederick C. Waite. Cloth. $3. Pp. 132. Boston University School of Medicine, 80 E. Concord St., Boston 18, 1950.

In the preface and in chapter one, the author points out that the establishment about 100 years ago of a female medical college was part of a public agitation for woman's rights, which had been going on in the United States since 1836. By 1848, the number of agitators had increased to such an extent that a national convention was held, at which the right of women to enter the profession of medicine was advocated. Other liberalizing movements got under way about this time. The first homeopathic medical college was founded in the United States in 1836. Thomsonianism, a cult of botanic medicine, which had been rampant since the early 1820's, disintegrated in 1843, and from its remnants arose electicism, another cult, the keystone of which was the administration of only one drug at a time. The vagaries of mesmerism, phrenology, spiritualism, and animal magnetism tried to attach themselves to medicine, but they soon disappeared. A semblance of order was brought about by the organization of the American Medical Association in 1847. In 1848, instruction began in the first institution in the United States for teaching medical subjects to women, the Boston Female Medical College. This institution changed its name in 1851 to the New England Female Medical College. In writing this history, the author derives his information from the complete manuscript records of the trustees and faculty, from a nearly

---

The reviews here published have been prepared by competent authorities and do not represent the opinions of any official bodies unless specifically stated.

complete file of reports and catalogues, from official records of legislative actions, and from articles in medical journals and newspapers. The American Medical Directory classifies the New England Female Medical College as homeopathic, but the author states (page 87) in discussing its graduates that "A point of interest is whether these graduates, educated in an institution where regular (allopathic) therapeutics was taught, continued to be regular in their practice or became allied with one of the medical sects. . . . The practice of women physicians was almost exclusively with women and children with whom the mild and tasty medicaments of homeopathy were popular. Therefore, it was not surprising that some of these graduates adopted homeopathic methods." Only 98 women received the degree of Doctor of Medicine from this college before it merged with the Boston School of Medicine in 1874.

Hemodynamics in Failure of the Circulation. By W. B. Youmans, M.D., Ph.D., Professor of Physiology, Department of Physiology, University of Oregon Medical School, Portland, and A. R. Huckins, M.S., M.D., Research Assistant, Department of Physiology, University of Oregon Medical School, Portland. Publication number 88, *American Lecture Series, monograph* in American Lectures in Physiology, edited by Robert F. Pitts, M.D., *Ph.D., Professor of Physiology,* Syracuse University College of Medicine, Syracuse, N. Y. Cloth. $2.75. Pp. 71, with 10 illustrations. *Charles C Thomas,* Publisher, 301-327 E. Lawrence Ave., Springfield, Ill.; Blackwell Scientific Publications, Ltd., 49 Broad St., Oxford, England; Ryerson Press, 299 Queen St., W., Toronto 2B, 1951.

This monograph describes in simple terms the present concept of heart failure. The authors have restricted the term "heart failure" to those conditions in which the heart is primarily involved. For those disturbances of circulation in which venous congestion is prominent and the cardiac output is increased, such as in the case of arteriovenous aneurysm and the so-called "beri beri heart," the term "chronic venous congestion without heart failure" is used. To one who has always been disturbed by the term "heart failure with high cardiac output" in cases in which the heart was not primarily involved, this new method of classification makes sense.

In order to make the total presentation as simple as possible, the authors have wisely refrained from long discussions on controversial matters. However, a bibliography consisting of two hundred references is available for those who wish to read further on the subject. The role of the kidney in the picture of congestive heart failure is well presented. The confusing terms of "backward" and "forward" failure are wisely omitted. Diagrams are used to show the effects of heart failure and schematically indicate the mechanisms concerned in the total picture. This monograph will be of considerable value to medical students and to those physicians who have not had an opportunity to review the voluminous literature on this subject in the past few years. It could also be read with profit by those who are working in the field of cardiovascular diseases.

Klinische Chemie und Mikroskopie: Ausgewählte Untersuchungsmethoden für das medizinisch-chemische Laboratorium. Von Dr. Lothar Hallmann. Sixth edition. Cloth. 24.60 marks; $5.85. Pp. 594, with 173 illustrations. Georg Thieme, Diemershaldenstrasse 47, (14a) Stuttgart O, 1950.

This well-organized book gives the information usually available in the standard textbooks of laboratory diagnosis in this country. The initial chapter deals with general technique of the clinical laboratory, with a special section devoted to reagents. The chapters following deal with the examination of saliva, gastric and duodenal content, feces, sputum, exudate, transudate, content of cysts and prostatic secretion, urine, spinal fluid, and blood. Included is a special chapter on normal values in blood, urine, and spinal fluid, and another one is devoted to micromethods. In an appendix, relatively few references to the literature (mostly German) are given and technical terms are explained. The entire presentation concentrates on description of methods, with relatively little theoretical discussion. In the selection of the methods, clinical application is kept in mind. Much use is made of tables and very good illustrations. The book is unusually well organized, and a surprising amount of information is compressed into a small space. Nevertheless, it mainly reflects the methods used at present in Germany, which are not necessarily identical with those used widely in the United States. Consequently, it is of only little value in the American laboratory.

Handbuch der Virusforschung. Herausgegeben von Prof. Dr. R. Doerr und Prof. Dr. C. Hallauer. II. Ergänzungsband. Bearbeitet von F. M. Burnet, et al. Cloth. $16.50. Pp. 425, with 187 illustrations. Springer-Verlag, Mölkerbastei 5, Wien 1, 1950.

This handbook contains a series of reviews by an international group of experts. Some chapters contain practical technical information; others discuss special problems such as the phenomenon of hemagglutination, virus pneumonia, variation in influenza viruses, and immunity in influenza. Almost half of the volume is devoted to an excellent review of electronmicroscopy in virus research by Helmut Ruska. This investigator compares electronmicroscopy with other methods, including other microscopic procedures, used in research on viruses. After a thorough discussion of principles, characteristics, limitations, and methodology, there is a report of findings of electronmicroscopic studies on protozoa, spirochetes, bacteria, rickettsiae, and viruses. This review contains a large number of very fine photographs of these agents prepared by the author and other investigators in Europe and America. The bibliography consist of more than 600 references.

A good bit of useful information is given in the chapters on roller tube tissue culture by A. E. Feller, on drying of viruses by E. W. Flosdorf, and application of reflected light and dark-field microscopy by M. Kaiser and P. Vonwiller. There is also a discussion of variation in influenza viruses by F. M. Burnet. This problem is of vital importance not only from the standpoint of better understanding of the nature and behavior of these viruses, but also from the point of view of practical considerations in the control and prevention of influenza as illustrated by the subsequent chapter by T. Francis Jr., who presents a timely subject, immunity and vaccination in influenza. A discussion bearing somewhat on the virus of influenza but covering comprehensively a phenomenon exhibited by several viruses and other agents is contained in a chapter by C. Hallauer. M. D. Eaton gives an interesting and extensive review of virus pneumonia and pneumonitis viruses of animals which are transmissible to man. The chapters by the European authors are in German; those by the American and Australian workers are in English. In addition to a table of contents, there is also a composite subject index.

Die suprapubische Prostatektomie mit primärem Blasenverschluss nach eigener Methode: Vorbereitung, Technik, Nachbehandlung. Von Univ.-Prof. Dr. Theodor Hryntschak, Vorstand der urologischen Abteilung der Wiener städtischen allgemeinen Poliklinik. Cloth. $5.70. Pp. 166, with 35 illustrations. Wilhelm Maudrich, Spitalgasse 1B, Wien 71, 1951.

This monograph is limited to a discussion of suprapubic prostatectomy with primary closure according to the technique devised by the author. A good historical review of the various methods used in bladder closure is presented, and as far as the author is able to determine, he is the first person to use purse string sutures in closing the bladder. In some instances he uses a cross stitch over the first purse string suture, over which he uses another purse string suture.

The author stresses the importance of close cooperation with the internist in the study of the cardiovascular system before the operation. In the preoperative preparation of the patient, he prefers to avoid the use of the indwelling catheter when there is no infection. He believes the use of the indwelling catheter predisposes to embolism and thrombosis, two conditions that play a large role in the cause of deaths. The importance of meticulousness in the postoperative management is stressed.

On the subject of bleeding after the operation, the author differentiates between the slight ooze from the wound bed, which can be controlled with a syringe at the patient's bedside, and the profuse bleeding, which necessitates opening the bladder to control it. The slight ooze from the prostatic bed he designates as "bleeding on the day of operation."

The author gives a detailed description of his operation and the manner in which it differs from the operation first proposed by Dr. Harris of Australia. The monograph contains a report of 100 cases of suprapubic prostatectomy with primary closure. There were four deaths, three of which were due to pulmonary embolism, and one was due to sepsis. In only one case did a suprapubic fistula develop. The author has also used this method of primary closure of the bladder in cases of foreign bodies, bladder stones, and bladder tumors. These are illustrated with brief case reports.

This monograph has been prepared in great detail. The printing is very good, and the illustrations, of which there are thirty-five, are excellent. The author has a vast experience and is well qualified to write this kind of book. To those interested in this type of prostatectomy, this book will be of great value.

Congenital Heart Disease. By James W. Brown, M.D., F.R.C.P., Physician to Grimsby General Hospital, Grimsby, England. Second edition. Cloth. $6; 30s. Pp. 344, with 128 illustrations. Staples Press, Ltd., Mandeville Place, London; 70 E. 45th St., New York 17, 1950.

In the eleven years since the first edition of the book was published, there have been so many important advances in diagnosis and treatment that this edition is largely rewritten and is, therefore, practically a new book. The author has described his own observations based on a large series of cases followed for many years. He has also quoted extensively from the literature and has included a well-chosen, fairly complete bibliography of the important literature. The common abnormalities, particularly those that can be recognized clinically, are given more prominence than rare lesions that can be diagnosed only at autopsy. Although information gained by catheterization is discussed adequately, angiocardiography is only briefly mentioned, chiefly because the author, as he himself states in the preface, has had little personal experience with the technique. The book is easy to read, even in the sections devoted to the more complicated congenital defects. The illustrations are simple and well chosen. The monograph is, therefore, a good reference book, not only for the cardiologist, but for any physician who has occasion to see a patient with congenital heart disease.

Human Biology. By George Alfred Baitsell, Colgate Professor of Biology, Yale University, New Haven. Second edition. Cloth. $6. Pp. 730, with 361 illustrations. McGraw-Hill Book Company, Inc., 330 W. 42nd St., New York 18; Aldwych House, Aldwych, London, W.C.2, 1950.

This book presents the subject of biology from the standpoint of that most interesting of organisms, man. The phenomena of animal and vegetable life are interpreted as to their significance to man and their resemblances to processes in the human body, and practically every aspect of human anatomy and physiology is compared with analogues among other living things, large and small. The treatment is kept from becoming unduly general and abstract by a wealth of illustrations, constant reference to specific examples in the text, and a remarkable 153 page appendix. This last consists largely of verbatim quotations from especially famous or well-written sources, such as Beaumont's description of the observations on St. Martin.

Very few minor faults are to be found; an example is the description of the stomach on page 56. The author would also be justified in adhering more consistently to the metric system, since the book is for college students. On the whole, it is a most commendable and substantial work.

Trends in Gerontology. By Nathan W. Shock, Chief, Section on Gerontology, National Heart Institute, United States Public Health Service. Cloth. $2.50. Pp. 153, with 12 illustrations. Stanford University Press, Stanford University, California, 1951.

Gerontology is defined as "the scientific study of the phenomena of aging." In this readable, informative book, Dr. Shock surveys present day problems, programs, and plans concerning older persons. An expansion of a preliminary report submitted to Stanford University in 1949, this volume discusses twelve topics: population, employment, income and retirement, health insurance, housing, education (public and professional), community programs, present activities in medical research, laboratories and institutions that are engaged in or planning research, needs in research, and a detailed outline of how an institute in gerontology should be organized and what it could do. Thus the [illegible] emphasis is on research. Not a clinical volume, this book serves as a summary and discussion of statistical, social, economic, community, and research phases of the "grave social problem" created by the rapid increase in number and proportion of our population of older persons. The book is noteworthy if only for its summary of current research in the biology, physiology, medicine, and sociology of aging.

Cornell Conferences on Therapy. Volume IV. Edited by Harry Gold, M.D., Managing Editor, and others. Cloth. $3.50. Pp. 342. The Macmillan Company, 60 Fifth Ave., New York 11, 1951.

The Cornell Conferences on Therapy were inaugurated in 1937 as a joint venture of the departments of medicine and pharmacology. The intention was to take up such topics as seemed of particular interest at the time. A conference is usually initiated with introductory remarks, but the discussion is, for the most part, extemporaneous. The aim, according to its editors, was limited to the exploration of some aspects of special interest, analysis of the evidence on controversial points of opinion and practice, elaboration of the physiologic, pharmacologic, and chemical basis of therapeutic measures, and presentation of these on the level of the general practitioner. After the first year's experience, it was felt that a permanent record would enhance the value of these conferences. Accordingly, the proceedings were taken down by a stenotypist. The next step in the evolution of these records was their monthly publication from 1937 to 1940 in The Journal. In 1940, the publication was transferred to the *New York State Journal of Medicine* and still later to the *American Journal of Medicine.* Since 1946, the plan was adopted to print one conference every other month in the *New York State Journal of Medicine* and one every other month in the *American Journal of Medicine.* The final step in the evolution of the conferences was their annual publication in a volume reporting a group of conferences selected for their quality and value.

The "conferences" published in this volume reflect the variety of topics that come under discussion. "Household Poisonings," "Management of Disorders of Cardiac Rhythm," "Medical Management of Hypertension," "Therapeutic Uses of Gamma Globulin," and "Management of the Menopause" are some of the fifteen topics covered in this volume. The nature of the discussion is preeminently practical. The information which is supplied by experts in a given field is valuable and is up-to-date. Each conference is terminated by a summary. The small volume should prove of great interest both to the internist and to the general practitioner.

The Student's Handbook of Surgical Operations. By Sir Frederick Treves, Bart., G.C.V.O., C.B., Ninth edition, revised by Sir Cecil Wakeley, K.B.E., C.B., D.Sc., Senior Surgeon to King's College Hospital, London. Cloth. $5.50. Pp. 580, with 269 illustrations. Paul B. Hoeber, Inc. (Medical Book Department of Harper & Brothers), 49 E. 33rd St., New York 16, 1951.

The popularity of this book is attested by the fact that since its first appearance in 1892, it has gone through eight additional publications. The new edition has been thoroughly revised, many new illustrations have been added, and the text has been brought up-to-date. Many of the old illustrations have been replaced by modern ones. This handy little volume of some 500 pages covers the entire field of surgery in a somewhat condensed but otherwise satisfactory manner so far as the student is concerned. In conformity with the older textbooks, part one consists of "Ligature of Arteries." The importance of this procedure in the light of modern surgery is probably secondary. This particular chapter could be left out. The print and the illustrations are satisfactory.

Health and Human Relations in Germany. Report of Conference on Problems of Health and Human Relations in Germany, Nassau Tavern, Princeton, N. J., June 26-30, 1950. Paper. $1. Pp. 207. Josiah Macy, Jr. Foundation, 565 Park Ave., New York 21; National Association for Mental Health, 1790 Broadway, New York 19, 1950.

This is a report of a conference attended by persons who have done work in Germany in connection with the United States Military Government, now High Commission for Germany, UNESCO, some British and French representatives, and a few Germans. Although "health" is first in the title, most of the volume is devoted to education and the function of the democratic process in relation to the German character. The report ought to be of wide interest but probably will not be, because the indications are that, despite the recommendations of qualified persons who have been in Germany, the policy of the United States seems to be constant curtailment of personnel and funds through which human relations and health progress in Germany could be fostered.

QUERIES AND MINOR NOTES

SUDDEN SEVERE PRECORDIAL PAIN

To the Editor:—*Eight months ago a patient experienced sudden, severe, persistent precordial pain. He had some ashy pallor, bradycardia followed by tachycardia and temperature of 100 F. on admission to the hospital. There was no dyspnea; the skin was cool, clammy and moist. He had a duodenal ulcer of 18 months' duration, although positive x-ray findings were noted one month preceding sudden onset of pain in the chest. Sedimentation time was 15 and the leukocyte count 8,500; the temperature was normal in 12 hours. An electrocardiogram showed slight elevation of the RS-T interval. The patient was out of bed in two weeks and home in four weeks. An unusual symptom was prolonged tenderness of the chest wall anteriorly and posteriorly and inability to lie on either side. Chair back pressure on the left scapula was painful, causing acute soreness. After eight months, however, the soreness disappeared. The patient used banthine® for the duodenal ulcer but discontinued it because of precordial distress, similar to that induced by exercise. The cardiologist was not convinced that the patient had a coronary occlusion. Heparin and dicumarol were used. Graduated exercise is now in progress, with discontinuance short of fatigue. Do you concur with the general plan of treatment? How long should the rest period be continued before gradual return to light activity? I have never encountered a case before with such acute chest wall tenderness.*

Everett D. Hockenberry, M.D., Coral Gables, Fla.

Answer.—It seems that acute coronary occlusion with little or no myocardial infarction can best explain the severe illness eight months ago. The tenderness of the chest wall is not easily explained, because most patients with disease of heart or lungs do not have such tenderness. Nervously sensitive persons, however, who are subject to neurocirculatory asthenia frequently show tenderness of the chest wall. Rest in bed can result in muscular or joint soreness, due perhaps to posture or to actual arthritis, myositis or neuritis, generally temporary in duration. When full activity is resumed, these symptoms usually clear up. It would be important to know the details of serial electrocardiograms, in which leads the RS-T intervals were elevated, and what progressive changes were shown in repeated records.

Another possible explanation of the prolonged pain and tenderness around the left chest (back as well as front) is that of an initial or primary or of a complicating herpes zoster although no note was made of any skin eruption therefrom if it was present. A direct nerve origin of these troublesome symptoms seems quite logical.

The therapy of the attack seems to have been adequate. Advice as to future activity must depend on the coronary reserve. If certain physical or nervous strain brings on angina pectoris, such strain should be avoided. Care must be taken to rule out other causes of discomfort, such as neurocirculatory asthenia and the peptic ulcer itself. It would not seem necessary to continue the rest period for the heart now except for avoidance of strains that might produce angina pectoris. It does not take many weeks for the complete healing of a myocardial infarct. Sometimes, however, months or years pass before angina pectoris yields to the natural development of an adequate collateral circulation, and sometimes angina pectoris recurs persistently for the duration of life but can be tolerated by avoidance of strain and the use of nitrites.

The answers here published have been prepared by competent authorities. They do not, however, represent the opinions of any official bodies unless specifically stated in the reply. Anonymous communications and queries on postal cards cannot be answered. Every letter must contain the writer's name and address, but these will be omitted on request.

PERSISTENT SALTY TASTE

To the Editor:—*A 57 year old white man has had an annoying salty taste in his mouth for three years. The symptom started while he was having teeth removed for pyorrhea and persisted after removal of all teeth and after he was fitted with full upper and lower acrylic dentures. It is so annoying that he constantly sucks on candy or chews gum. He uses no salt on his food. He is in good health except for a traumatic glaucoma, for which he has been using 25 per cent pilocarpine, one drop daily in the right eye for seven years. The blood is normal except for 5 per cent eosinophils. The urine is normal. No oral lesions or systemic diseases were detected on physical examination. I should like an opinion on diagnosis and suggestions for further study.*

Robert A. Marks Jr., M.D., Buffalo.

Answer.—If the timing of the onset of symptoms is correct and the mouth condition is normal, several possible causes can be ruled out. The constant salty taste should have no relation to the previous use of pilocarpine or the later use of dentures. Pilocarpine produces an increase in saliva, but the dose in use is so small and infrequent that it is not probable that it could be effective on a single type of taste bud in the mouth. The salty taste aberration could not be explained on a basis of nerve change or injury at the time of extraction. Taste changes may occur between the ages of 50 and 70 as a part of senescence but are usually due to lowered sensitivity, especially if the palate is covered by a plate. Subclinical glossitis can produce taste abnormality, as described in the answer to a query in The Journal of Sept. 17, 1949 (page 237). Saliva contains taste-activating hormones, but the use of salivary depressants and stimulants to determine the effect of saliva volume on taste might disturb the glaucoma. The persistence of the salty taste suggests a psychoneurotic etiology, and a capable neuropsychiatrist could check both the nerve and psychic aspects.

DUODENAL ULCER IN DIFFERENT RACES

To the Editor:—*Is there any particular race subject to duodenal ulcer, and what are the ratios in the different races?*

Benjamin Berger, M.D., New York.

Answer.—Data concerning the racial incidence of duodenal ulcer are not as plentiful as is indicated by the importance of the question. In 1945, L. G. Rowntree, in analyzing a large number of selective service registrants, reported a 0.52 per cent incidence of peptic ulcer in white troops as compared with 0.14 per cent in Negroes. A detailed analysis of this problem is presented in the book on peptic ulcer by A. C. Ivy, M. I. Grossman and W. H. Bachrach (New York, The Blakiston Company, 1950). According to these authors, the findings obtained as a result of a large series of autopsies performed on a group of Chinese and Javanese male laborers in Sumatra revealed profound differences. Thus in 1,370 autopsies on the Chinese laborers, 151 ulcers or scars of ulcers were found, an incidence of 11 per cent. On the other hand, in 1,269 Javanese laborers examined postmortem, ulcers or scars of ulcers were found in only 8, an incidence of 0.6 per cent. The authors quote Bonne as noting that absence of visible emotion is rather characteristic of the Malay race. This study in Sumatra is valuable in that the comparison was made between two races with subjects of the same sex and similar occupation. With the increasing evidence that environmental factors, such as occupation and subjection to stress and strain, play such an important role in the disease, before one can attribute variations in incidence of peptic ulcer to differences in race, it is essential that comparisons be made between persons of the same sex and subjected to the same environmental pressures. Although a general impression exists that the incidence of duodenal ulcer in Negroes in the United States is significantly less than in the white race, this difference has become much less pronounced when environmental factors have been about the same.

BONE CYSTS

To THE EDITOR:—*A 17 year old boy is 12 pounds (5 Kg.) overweight; his height is 70 inches (178 cm.), blood calcium 10.6 mg. and blood phosphorus 3.4 mg. X-ray reveals a normal pituitary; the lower ends of both femurs show small partly healed bone cysts and slight osteoporosis; the lower end of the right tibia shows a solitary, partly healed bone cyst. The diagnosis probably is hyperparathyroidism (von Recklinghausen), but the parathyroids are not palpable. Would use of calcium gluconate be advisable? A diet rich in calcium and phosphorus was given. What is the best treatment? How can one exclude a tumor or hyperplasia of the parathyroid?*

Jacob Aisenstat, M.D., New York.

This inquiry was referred to two authorities, whose respective replies follow.—ED.

ANSWER.—With normal serum calcium and serum phosphorus levels, hyperparathyroidism is unlikely. There is nothing in the query to suggest that there is generalized demineralization of bone. One would have to consider polyostotic fibrous dysplasia. The most likely diagnosis from the facts at hand is neurofibromatosis with bone involvement. The lower ends of the femurs are apt to be involved in this condition. The same is true of the lower thirds of the tibias. The fact that the parathyroids are not palpable is of no significance in ruling out hyperparathyroidism. The treatment in this case depends on the diagnosis. The diagnosis would be strengthened if café au lait areas of pigmentation or subcutaneous neurofibromas could be demonstrated.

ANSWER.—One should make calcium balance studies in order to observe the excretion of calcium on an inadequate calcium intake. Concentration of calcium and phosphorus in serum appear to be within normal limits, but further studies should be made. Hyperparathyroidism may be present without a palpable tumor in the neck. Enlarged parathyroid glands may be found in the mediastinum or buried in the thyroid. Parathyroid tumors may be so small that they are difficult to palpate even though they are present in the usual location. Hyperparathyroidism may be associated with hyperplasia of the parathyroid glands without much enlargement. The development of bone cysts does not necessarily mean that hyperparathyroidism is present, but they do mean that every effort should be made to exclude this condition. If hyperfunction of the parathyroid glands is not present, it would seem logical to administer fairly large doses of calcium supplemented by vitamin D.

NYMPHOMANIA

To THE EDITOR:—*A 30 year old married woman had a subtotal hysterectomy seven years ago. Three months ago she complained of irritability and hot flashes and was given estrogens with relief. She then complained that she had had excessive libido for six years. On cessation of treatment with estrogens, hot flashes returned but excessive libido remains. She states that full orgasm is reached at each intercourse and that she is forced to awaken her husband two to three times per night to satisfy her desire. She cannot go to dances and even avoids men on the street, as this produces painful pelvic congestion. Pelvic examination reveals no masses. Please help me with the etiology of this condition and treatment in this case.*

M.D., Colorado.

ANSWER.—It was unfortunate this woman had her uterus removed when she was only 23 years of age, but most likely this operation has nothing to do with the present disturbance. The patient has nymphomania; this is not related to the use of estrogens. The usual basis for this serious condition is a psychic disturbance; hence psychotherapy should be instituted without delay.

CESAREAN SECTION

To THE EDITOR:—*Is there any exception to the rule "Once a cesarean section, always a cesarean section?"*

Walter A. Landry, M.D., Chester, Pa.

ANSWER.—The dictum, "Once a cesarean section, always a cesarean section," is by no means universally followed. Several reports have been published dealing with cases in which vaginal delivery was carried out after previous cesarean section.

J. P. Greenhill in the 1949 "Year Book of Obstetrics and Gynecology," page 227, says, "Whenever a cesarean section is performed, the question arises: Shall a woman who has once had a cesarean section always have a cesarean section? Formerly I delivered many women through the vagina who had previously had cesarean sections. However, the risk from cesarean section is so slight that I do not believe it worthwhile to chance rupture of the uterus, regardless of what the indication was for the first operation. I therefore almost routinely perform a repeat cesarean section. Of course, if a baby is small in a subsequent pregnancy and the woman goes into labor spontaneously and if she is in a hospital where she can be watched carefully, labor may be permitted to proceed. But even under these conditions, I would feel ill at ease, despite the excellent results obtained by some obstetricians. One can never be certain that rupture will not take place, though rupture of the uterus during pregnancy is extremely rare after cervical cesarean section. On the other hand, after classic operation, rupture of the uterus at seven to nine months is not too uncommon. The death rate from rupture is extremely high, whereas that from repeat cesarean section is almost negligible, because most of these operations are elective and performed when the patient is in good condition."

DEAD FETUS

To THE EDITOR:—*A young bipara was delivered of a dead, slightly macerated fetus. Her first baby was normal, and there were no complications during her period of gestation. Her second pregnancy was equally uncomplicated. She went to full term; she felt violent fetal activity three days before the birth of this child and none afterward. The delivery was uneventful. Is it possible that this infant started to breathe in utero at the time she felt the violent fetal activity? On delivery there was discolored amniotic fluid coming from the lungs.*

M.D., Pennsylvania.

ANSWER.—In most cases, like the one described, it is not possible to determine the exact cause of death of the fetus even when an autopsy is performed on the macerated fetus. In a few instances there is separation of the placenta, but nearly always there is some external bleeding to indicate the condition. Furthermore, in such cases, when the placenta is delivered, some blood clots will be found attached to the maternal surface of the placenta. Discolored amniotic fluid is nearly always present when the fetus is macerated. The finding of amniotic fluid in the lungs or escaping from the lungs has no significance, because amniotic fluid can be aspirated into the lungs of normal babies owing to the intrauterine respiratory movements which most likely occur in all babies during their intrauterine existence.

MANURE ON A FOOTBALL FIELD

To THE EDITOR:—*The school board is contemplating using barnyard manure to fertilize the football field. What is the possibility of tetanus being contracted by the players?*

A. L. Delaney, M.D., Liberty, Texas.

ANSWER.—The use of manure on a football field is definitely contraindicated, in view of the high incidence of tetanus following contamination of skin injuries with the spores of Clostridium tetani contained in manure. Moreover, it would be desirable that all the players be immunized with tetanus toxoid in order that the possibility of their contracting clinical tetanus under all conditions of play be minimized.

DWARFISM

To the Editor:—*A 4 year old girl, has been well except for chickenpox and whooping cough at the age of 3 years and at five months, respectively. Birth weight was 7 pound 3 ounces (3,260 Gm.). Since the age of 1 year, the child has grown very little. Her present weight is 22 pounds (10 Kg.). Physical examination disclosed no abnormalities, and the child was mentally alert. Four repeated urinalyses have shown albumen (3 plus) and sugar (3 and 4 plus) with no acetone and normal specific gravity and miscroscopic findings. Fasting blood sugar was 92 mg. Medical advice was sought mainly because of the child's poor appetite. Please suggest further diagnostic procedure and treatment.*

M.D., New Mexico.

Answer.—A 4 year old child weighing only 22 pounds must be extremely short and have the general conformation of a dwarf. The height-weight-age tables of Bird T. Baldwin and Thomas D. Wood present the lowest weight for a female of 4 years and under 5 years as 25½ pounds (11.53 Kg.) with a height of 33 inches (83.82 cm.) Dwarfism may fall into a number of categories as (*a*) ateliosis, or true infantilism, characterized by childish skeletal, genital, and mental development, (*b*) primordial dwarfism, present at birth and with normal osseous, sex and mental development and (*c*) renal rickets or dwarfism, which is not true dwarfism but is due to impairment of bone growth from hyperparathyroidism. There are associated urinary disturbances with renal rickets, including glycosuria. Other types are achondroplastic dwarfism, cretinism from congenital hypothyroidism and endocrine dwarfism, particularly that due to hypopituitarism. Other causes of dwarfism, or retarded growth, are pancreatic deficiencies, sprue, celiac disease, encephalitis and various bone dystrophies.

The cause of the glycosuria with a fasting blood sugar within normal range (70-100 mg. per 100 cc.) may be diabetes mellitus. Renal diabetes, fright, excessive consumption of easily assimilable carbohydrates, renal dwarfism and pentosuria may be other causes of glycosuria. For differentiation, the type of sugar should be identified, and several glucose tolerance tests should be performed in case the curve suggests true diabetes.

Albuminuria may be due to various causes, among which are orthostatic albuminuria, which is symptomless; pyuria; nephritis; nephrosis; renal dwarfism, and Bence-Jones proteinuria.

The three major signs presented, dwarfism, glycosuria and albuminuria are all common to renal dwarfism. If the diagnosis of this condition can be established, nephritic therapy, large amounts of vitamins A and D, sufficient alkali, particularly potassium, and removal of a parathyroid tumor, if present, would constitute adequate treatment. If the diagnosis of diabetes mellitus is established, hospitalization with an attempt to control the disease by proper diet should be made before insulin therapy is instituted. The normal urinary specific gravity would make the diagnosis of nephritis or diabetes doubtful.

HORMONE TREATMENT FOR BLEEDING FIBROID UTERUS

To the Editor:—*Will any hormone treatment—estrogen or testosterone—stop bleeding from a fibroid uterus? Will it affect the size of the fibroid?*

Lewis W. Berry, M.D., Chelan, Wash.

Answer.—Both estrogen and testosterone can stop bleeding from a fibroid uterus temporarily. Likewise, enormous amounts of testosterone can produce a slight decrease in the size of fibromyomas, but this also is temporary. It is useless to employ endocrine therapy to reduce the size of a fibroid uterus, because the necessary doses are far beyond safety. In almost all instances in which any appreciable effect can be observed on a fibromyomatous uterus, signs of virilism appear. These include excessive hair growth on the face, change in voice and enlargement of the clitoris. Bleeding associated with a fibroid uterus does not arise in the myomas but comes from associated changes in the endometrium. In all instances of profuse or irregular bleeding, regardless of whether fibromyomas are present, cancer must be ruled out.

EXCESS GAS IN INTESTINE

To the Editor:—*A patient continually complains about gas formation in the intestines. He has had a complete examination, with negative results except for a tremendous number of Trichomonas in the stool. Years ago he spent a long time in a tuberculosis sanitarium. Could these Trichomonas become pathogenic? What would be the treatment? I have been giving him turpentine 0.6 cc. three times a day. The patient has no dysentery, but gas formation is often accompanied by unformed stools.* *M.D., Illinois.*

Answer.—The role of Trichomonas vaginalis or hominis as intestinal pathogens has not been clearly established. Usually, if a careful stool examination by a qualified observer is made on a patient with diarrhea or dysentery, some other cause is found. As yet no cyst forms of T. hominis have been discovered in solid stools.

Verified cases of intestinal infection due to Trichomonas vaginalis apparently have not been reported, and it is possible that the organism mentioned in this case is actually T. hominis, since these varieties are morphologically similar. The treatment of Trichomonas hominis infection is unsatisfactory; however, the most efficacious agents are diiodohydroxyquinoline (diodoquin®) and carbarsone as used in amebiasis. A trial of diiodohydroxyquinoline therapy would be of interest in the case described.

The writer is referred to the following sources for more detailed information: Portis, S. A.: "Diseases of the Digestive System," Lea & Febiger, Philadelphia, 1944 ed. 2, pp. 592-595; Belding, D. L. "Textbook of Clinical Parasitology," D. Appleton-Century Co., New York 1942; Jordan, E., & Burrows, W. "Textbook of Bacteriology, ed. 14 revised, W. B. Saunders Co., Philadelphia, 1944.

LACTOSURIA

To the Editor:—*Is there a simple office method for distinguishing between lactosuria and glycosuria in obstetric patients? At what stage of pregnancy is lactosuria to be expected?* *M. M. Young, M.D., Crossville, Tenn.*

Answer.—There are three ways of determining the difference between lactosuria and glycosuria. The tests for lactosuria are (1) the phenylhydrazine test (crystal test), (2) the Rubner (color test) and (3) the fermentation test. The technics of these tests may be found in books on laboratory procedures, for example, "Clinical Diagnosis by Laboratory Methods" by J. C. Todd and A. H. Sanford, and "Manual of Clinical Laboratory Methods" by O. E. Hepler.

The finding of sufficient lactose in the urine to produce a faint Benedict reaction occurs in about 1 to 2 per cent of pregnant women before the last six weeks of gestation. During the last six weeks of pregnancy the frequency of lactosuria is about 7 or 8 per cent. On the day before delivery the incidence is about 30 per cent. Of course, lactosuria is much commoner and more pronounced after delivery. During the first few days of the puerperium, the majority of women show lactosuria, often in large amounts. This fact must be taken into consideration when diabetic women are studied after delivery.

OPHTHALMIC OINTMENT BASE

To the Editor:—*What is the most suitable ophthalmic ointment base? Is aquaphor® and water all right?*

Walter Weinberger, M.D., Juniata, Altoona, Pa.

Answer.—As a suitable ophthalmic ointment base aquaphor® with water is usually satisfactory. However, in many instances anhydrous bases are more suitable and are required with certain drugs commonly used for local application to the eye. Such drugs as penicillin and eserine will fit in this category. For this reason, a base consisting of 25 per cent wool fat, 50 per cent petrolatum and 25 per cent liquid petrolatum might be considered more suitable. This base has proper consistency and spreading action. In many instances aqueous bases are not desirable, since the liberation of the drug from the base is too rapid to accomplish suitable therapeusis. In these instances the base delineated above is more suitable.

between persons of the same sex and subjected to the same environmental pressures. Although a general impression exists that the incidence of duodenal ulcer in Negroes in the United States is significantly less than in the white race, this difference has become much less pronounced when environmental factors have been about the same.

BONE CYSTS

To the Editor:—*A 17 year old boy is 12 pounds (5 Kg.) overweight; his height is 70 inches (178 cm.), blood calcium 10.6 mg. and blood phosphorus 3.4 mg. X-ray reveals a normal pituitary; the lower ends of both femurs show small partly healed bone cysts and slight osteoporosis; the lower end of the right tibia shows a solitary, partly healed bone cyst. The diagnosis probably is hyperparathyroidism (von Recklinghausen), but the parathyroids are not palpable. Would use of calcium gluconate be advisable? A diet rich in calcium and phosphorus was given. What is the best treatment? How can one exclude a tumor or hyperplasia of the parathyroid?*

Jacob Aisenstat, M.D., New York.

This inquiry was referred to two authorities, whose respective replies follow.—Ed.

Answer.—With normal serum calcium and serum phosphorus levels, hyperparathyroidism is unlikely. There is nothing in the query to suggest that there is generalized demineralization of bone. One would have to consider polyostotic fibrous dysplasia. The most likely diagnosis from the facts at hand is neurofibromatosis with bone involvement. The lower ends of the femurs are apt to be involved in this condition. The same is true of the lower thirds of the tibias. The fact that the parathyroids are not palpable is of no significance in ruling out hyperparathyroidism. The treatment in this case depends on the diagnosis. The diagnosis would be strengthened if café au lait areas of pigmentation or subcutaneous neurofibromas could be demonstrated.

Answer.—One should make calcium balance studies in order to observe the excretion of calcium on an inadequate calcium intake. Concentration of calcium and phosphorus in serum appear to be within normal limits, but further studies should be made. Hyperparathyroidism may be present without a palpable tumor in the neck. Enlarged parathyroid glands may be found in the mediastinum or buried in the thyroid. Parathyroid tumors may be so small that they are difficult to palpate even though they are present in the usual location. Hyperparathyroidism may be associated with hyperplasia of the parathyroid glands without much enlargement. The development of bone cysts does not necessarily mean that hyperparathyroidism is present, but they do mean that every effort should be made to exclude this condition. If hyperfunction of the parathyroid glands is not present, it would seem logical to administer fairly large doses of calcium supplemented by vitamin D.

Please help me with the etiology of this condition and treatment in this case.*

M.D., Colorado.

Answer.—It was unfortunate this woman had her uterus removed when she was only 23 years of age, but most likely this operation has nothing to do with the present disturbance. The patient has nymphomania; this is not related to the use of estrogens. The usual basis for this serious condition is a psychic disturbance; hence psychotherapy should be instituted without delay.

CESAREAN SECTION

To the Editor:—*Is there any exception to the rule "Once a cesarean section, always a cesarean section?"*

Walter A. Landry, M.D., Chester, Pa.

Answer.—The dictum, "Once a cesarean section, always a cesarean section," is by no means universally followed. Several reports have been published dealing with cases in which vaginal delivery was carried out after previous cesarean section.

J. P. Greenhill in the 1949 "Year Book of Obstetrics and Gynecology," page 227, says, "Whenever a cesarean section is performed, the question arises: Shall a woman who has once had a cesarean section always have a cesarean section? Formerly I delivered many women through the vagina who had previously had cesarean sections. However, the risk from cesarean section is so slight that I do not believe it worthwhile to chance rupture of the uterus, regardless of what the indication was for the first operation. I therefore almost routinely perform a repeat cesarean section. Of course, if a baby is small in a subsequent pregnancy and the woman goes into labor spontaneously and if she is in a hospital where she can be watched carefully, labor may be permitted to proceed. But even under these conditions, I would feel ill at ease, despite the excellent results obtained by some obstetricians. One can never be certain that rupture will not take place, though rupture of the uterus during pregnancy is extremely rare after cervical cesarean section. On the other hand, after classic operation, rupture of the uterus at seven to nine months is not too uncommon. The death rate from rupture is extremely high, whereas that from repeat cesarean section is almost negligible, because most of these operations are elective and performed when the patient is in good condition."

DEAD FETUS

To the Editor:—*A young bipara was delivered of a dead, slightly macerated fetus. Her first baby was normal, and there were no complications during her period of gestation. Her second pregnancy was equally uncomplicated. She went to full term; she felt violent fetal activity three days before the birth of this child and none afterward. The delivery was uneventful. Is it possible that this infant started to breathe in utero at the time she felt the violent fetal activity? On delivery there was discolored amniotic fluid coming from the lungs.*

M.D., Pennsylvania.

Answer.—In most cases, like the one described, it is not possible to determine the exact cause of death of the fetus even when an autopsy is performed on the macerated fetus. In a few instances there is separation of the placenta, but nearly always there is some external bleeding to indicate the condition. Furthermore, in such cases, when the placenta is delivered, some blood clots will be found attached to the maternal surface of the placenta. Discolored amniotic fluid is nearly always present when the fetus is macerated. The finding of amniotic fluid in the lungs or escaping from the lungs has no significance, because amniotic fluid can be aspirated into the lungs of normal babies owing to the intrauterine respiratory movements which most likely occur in all babies during their intrauterine existence.

MANURE ON A FOOTBALL FIELD

To the Editor:—*The school board is contemplating using barnyard manure to fertilize the football field. What is the possibility of tetanus being contracted by the players?*

A. L. Delaney, M.D., Liberty, Texas.

Answer.—The use of manure on a football field is definitely contraindicated, in view of the high incidence of tetanus following contamination of skin injuries with the spores of Clostridium tetani contained in manure. Moreover, it would be desirable that all the players be immunized with tetanus toxoid in order that the possibility of their contracting clinical tetanus under all conditions of play be minimized.

DWARFISM

To the Editor:—*A 4 year old girl, has been well except for chickenpox and whooping cough at the age of 3 years and at five months, respectively. Birth weight was 7 pound 3 ounces (3,260 Gm.). Since the age of 1 year, the child has grown very little. Her present weight is 22 pounds (10 Kg.). Physical examination disclosed no abnormalities, and the child was mentally alert. Four repeated urinalyses have shown albumen (3 plus) and sugar (3 and 4 plus) with no acetone and normal specific gravity and miscroscopic findings. Fasting blood sugar was 92 mg. Medical advice was sought mainly because of the child's poor appetite. Please suggest further diagnostic procedure and treatment.*

M.D., New Mexico.

Answer.—A 4 year old child weighing only 22 pounds must be extremely short and have the general conformation of a dwarf. The height-weight-age tables of Bird T. Baldwin and Thomas D. Wood present the lowest weight for a female of 4 years and under 5 years as 25½ pounds (11.53 Kg.) with a height of 33 inches (83.82 cm.) Dwarfism may fall into a number of categories as (*a*) ateliosis, or true infantilism, characterized by childish skeletal, genital, and mental development, (*b*) primordial dwarfism, present at birth and with normal osseous, sex and mental development and (*c*) renal rickets or dwarfism, which is not true dwarfism but is due to impairment of bone growth from hyperparathyroidism. There are associated urinary disturbances with renal rickets, including glycosuria. Other types are achondroplastic dwarfism, cretinism from congenital hypothyroidism and endocrine dwarfism, particularly that due to hypopituitarism. Other causes of dwarfism, or retarded growth, are pancreatic deficiencies, sprue, celiac disease, encephalitis and various bone dystrophies.

The cause of the glycosuria with a fasting blood sugar within normal range (70-100 mg. per 100 cc.) may be diabetes mellitus. Renal diabetes, fright, excessive consumption of easily assimilable carbohydrates, renal dwarfism and pentosuria may be other causes of glycosuria. For differentiation, the type of sugar should be identified, and several glucose tolerance tests should be performed in case the curve suggests true diabetes.

Albuminuria may be due to various causes, among which are orthostatic albuminuria, which is symptomless; pyuria; nephritis; nephrosis; renal dwarfism, and Bence-Jones proteinuria.

The three major signs presented, dwarfism, glycosuria and albuminuria are all common to renal dwarfism. If the diagnosis of this condition can be established, nephritic therapy, large amounts of vitamins A and D, sufficient alkali, particularly potassium, and removal of a parathyroid tumor, if present, would constitute adequate treatment. If the diagnosis of diabetes mellitus is established, hospitalization with an attempt to control the disease by proper diet should be made before insulin therapy is instituted. The normal urinary specific gravity would make the diagnosis of nephritis or diabetes doubtful.

HORMONE TREATMENT FOR BLEEDING FIBROID UTERUS

To the Editor:—*Will any hormone treatment—estrogen or testosterone—stop bleeding from a fibroid uterus? Will it affect the size of the fibroid?*

Lewis W. Berry, M.D., Chelan, Wash.

Answer.—Both estrogen and testosterone can stop bleeding from a fibroid uterus temporarily. Likewise, enormous amounts of testosterone can produce a slight decrease in the size of fibromyomas, but this also is temporary. It is useless to employ endocrine therapy to reduce the size of a fibroid uterus, because the necessary doses are far beyond safety. In almost all instances in which any appreciable effect can be observed on a fibromyomatous uterus, signs of virilism appear. These include excessive hair growth on the face, change in voice and enlargement of the clitoris. Bleeding associated with a fibroid uterus does not arise in the myomas but comes from associated changes in the endometrium. In all instances of profuse or irregular bleeding, regardless of whether fibromyomas are present, cancer must be ruled out.

EXCESS GAS IN INTESTINE

To the Editor:—*A patient continually complains about gas formation in the intestines. He has had a complete examination, with negative results except for a tremendous number of Trichomonas in the stool. Years ago he spent a long time in a tuberculosis sanitarium. Could these Trichomonas become pathogenic? What would be the treatment? I have been giving him turpentine 0.6 cc. three times a day. The patient has no dysentery, but gas formation is often accompanied by unformed stools.* *M.D., Illinois.*

Answer.—The role of Trichomonas vaginalis or hominis as intestinal pathogens has not been clearly established. Usually, if a careful stool examination by a qualified observer is made on a patient with diarrhea or dysentery, some other cause is found. As yet no cyst forms of T. hominis have been discovered in solid stools.

Verified cases of intestinal infection due to Trichomonas vaginalis apparently have not been reported, and it is possible that the organism mentioned in this case is actually T. hominis, since these varieties are morphologically similar. The treatment of Trichomonas hominis infection [illegible] ever, the most efficacious agents are [illegible] (diodoquin®) and carbarsone as used in amebiasis. A trial of diiodohydroxyquinoline therapy would be of interest in the case described.

LACTOSURIA

To the Editor:—*Is there a simple office method for distinguishing between lactosuria and glycosuria in obstetric patients? At what stage of pregnancy is lactosuria to be expected?* *M. M. Young, M.D., Crossville, Tenn.*

Answer.—There are three ways of determining the difference between lactosuria and glycosuria. The tests for lactosuria are (1) the phenylhydrazine test (crystal test), (2) the Rubner (color test) and (3) the fermentation test. The technics of these tests may be found in books on laboratory procedures, for example, "Clinical Diagnosis by Laboratory Methods" by J. C. Todd and A. H. Sanford, and "Manual of Clinical Laboratory Methods" by O. E. Hepler.

The finding of sufficient lactose in the urine to produce a faint Benedict reaction occurs in about 1 to 2 per cent of pregnant women before the last six weeks of gestation. During the last six weeks of pregnancy the frequency of lactosuria is about 7 or 8 per cent. On the day before delivery the incidence is about 30 per cent. Of course, lactosuria is much commoner and more pronounced after delivery. During the first few days of the puerperium, the majority of women show lactosuria, often in large amounts. This fact must be taken into consideration when diabetic women are studied after delivery.

OPHTHALMIC OINTMENT BASE

To the Editor:—*What is the most suitable ophthalmic ointment base? Is aquaphor® and water all right?*

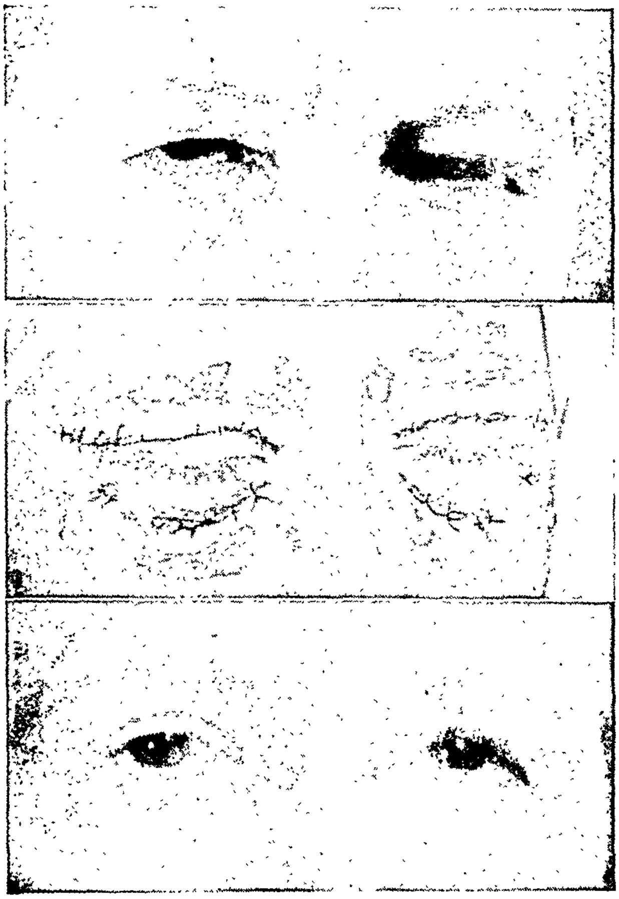
Walter Weinberger, M.D., Juniata, Altoona, Pa.

Answer.—As a suitable ophthalmic ointment base aquaphor® with water is usually satisfactory. However, in many instances anhydrous bases are more suitable and are required with certain drugs commonly used for local application to the eye. Such drugs as penicillin and eserine will fit in this category. For this reason, a base consisting of 25 per cent wool fat, 50 per cent petrolatum and 25 per cent liquid petrolatum might be considered more suitable. This base has proper consistency and spreading action. In many instances aqueous bases are not desirable, since the liberation of the drug from the base is too rapid to accomplish suitable therapeusis. In these instances the base delineated above is more suitable.

BAGS UNDER THE EYES

To the Editor:—*In* The Journal *of March 17 (page 858) Dr. Ursula Mandel asks for the cause of bags under the eyes and you give the exact replies of four authorities. All four of them may be correct in about one case out of a thousand. In the other 999, the cause is a familial tendency to localized lipodystrophy, with resultant partial herniation of encapsulated fat from within the intraorbital areas into the loose conjunctival tissue, occurring even in "teen agers."*

None of the authorities are quoting a remedy or curative procedure. Yet the cure is simple, direct and permanent. It consists of surgical removal of that amount of fat that is deemed excessive. Plastic surgeons interested in this phase do it regularly. The accompanying photographs illustrate the bagginess complained of (top), immediate postoperative display of fat overlying the area from which it was removed from upper and lower eyelids (center) and the results some weeks postoperatively (bottom).



H. O. Barnes, M.D.,
727 West Seventh Street,
Los Angeles 17.

To the Editor:—*In* The Journal *March 17, 1951, in Queries and Minor Notes, there appeared answers to the following question: "What is the cause of 'bags under the eyes,' which often occurs in patients with no kidney trouble or other known causes of the unsightly condition?"*

The Journal *stated, "This inquiry was referred to four authorities, whose respective replies follow." I was surprised to find clinical conditions listed, none of which actually and precisely answered the inquiry. In my practice as a plastic surgeon, I encounter this clinical state often. The "bags under the eyes" are not due to "edema," "muscle tone," "vasomotor states," "allergic responses," "familial traits," "atrophic changes in the epidermis or subcutaneous tissues." They are due to the presence of semiencapsulated periorbital adipose tissue which has protruded through a hiatus in the tarso-orbital fascia and can occur at any age, not only in elderly persons. The "adipose sac" varies in size, depending on whether or not the fat pad has become incarcerated. It is for this reason that daily changes, and changes throughout the day, in the size of these "bags" are often observed by the patients themselves.*

I have referred to this condition as "infraorbital adipocele"; similarly, "supraorbital adipocele" occurs. For 20 years I have removed "bags under the eyes," of the type described above, by means of the following surgical procedure, which I have designated "tarso-orbital fasciorrhaphy."

Starting at the inner canthus, I make an incision through the skin parallel with and about 1 to 1.5 mm. below the margin of the lower lid. This is extended to the outer canthus and continues for about 1 cm. lateralward, being placed in one of the natural laugh lines to minimize the scar. The skin is then undermined to about the level of the lower bony border of the orbital cavity. The fibers of the orbicularis oculi are then separated just above this level. As soon as this is done, a mass of semiencapsulated adipose tissue bulges forward through a herniation in the tarso-orbital fascia. This herniation is then enlarged, and all the protruding fat is excised. The tarso-orbital fascia is then imbricated with two or three C silk sutures. The redundant skin is then drawn up over the lid margin and the excess removed. Starting at the inner canthus, I unite the wound margins with a continuous C silk suture. Some trimming of the skin will be necessary at the outer canthus to insure a smooth union. In my experience, this plastic surgical procedure completely and permanently remedies this defect.

520 S. San Vicente Blvd., Los Angeles 48.

SPERMATOZOA AND VAGINAL ACIDITY

To the Editor:—*In reference to a Rhode Island physician's question, "Is it rare for pregnancy to result from a deposition of sperm on the vulva without intromission?"* (J. A. M. A. **145:**59 *[Jan. 6] 1951). I should like to say that it is not only extremely rare but very likely impossible. The three instances of impregnation, of two married women and an unmarried girl, quoted from "A Text-book of Obstetrics" by Barton Cooke Herst, submitted by Dr. Walter A. Landry, do not prove anything. There are many cases of unruptured hymens after complete intromission and according to Williams (Obstetrics, ed. 5, New York, D. Appleton-Century Company, Inc., 1923). "In rare instances the injuries resulting from childbirth are extremely slight, and very exceptionally are entirely lacking." Elsewhere, however, Williams states, "Some years ago I saw a patient in whom conception had occurred through a hymen which presented only a pin-point opening. . . ." With respect to all cases without intromission, and even this last case mentioned by Williams, it is my conviction that at the time of ejaculation the external urinary meatus (opening of the fossa navicularis of the penis) is in direct apposition with the hymeneal opening and that semen is thus forced into the vagina itself.*

GANGLION ON WRIST

To the Editor:—*Recently in Queries and Minor Notes, Dr. Bernard Weiss, New York, inquired about the treatment of ganglion of the wrist and requested suggestions as to nonsurgical treatment. Your answer failed to mention that treatment with x-rays is successful in a high percentage of cases. The only drawback is that it leaves a small area of increased pigmentation at the site of the ganglion. In many persons this disappears; in others it does not. I see many patients with this condition, and I have operated on only two in the last five or six years.*

TREATMENT OF SPONTANEOUS SUBARACHNOID HEMORRHAGE

Lester A. Mount, M.D., New York

Spontaneous subarachnoid hemorrhage is the nontraumatic extravasation of blood into the subarachnoid space. It is an episode in the course of an intracranial process and is not a disease entity. It is characterized, as a rule, by the sudden onset of severe headache, usually generalized, but most intense in the suboccipital or frontal region; vomiting; collapse, and coma in many instances. Stiffness of the neck then develops, and the patient may have other symptoms and signs due to pressure on adjacent structures. The commonest of these are pain on one side in the temporal or frontal region, double vision and drooping of one eyelid. These findings, of course, are the result of pressure on the fifth and third cranial nerves. There may be mental changes or abnormalities in strength, coordination, reflexes, sensation or functions of other cranial nerves. On the other hand, there may be no focal neurological signs or symptoms at all. Nuchal rigidity, a postive Kernig sign and bloody cerebrospinal fluid are constant findings. The introduction of the lumbar puncture by Quincke[1] in 1891 made the diagnosis easier.

The cause of spontaneous subarachnoid hemorrhage is the rupture of an intracranial aneurysm, either saccular or arteriovenous, in the great majority of cases. In 1765, Biumi[2] published the first report of a subarachnoid hemorrhage due to the rupture of an intracranial aneurysm. The aneurysm may be missed in a routine postmortem examination because, in the words of William Gull,[3] who described this specific point in 1859, "Recent coagula may so imbed and conceal it that, unless strictly looked for, it will not be found for the sac is often small and thin and transparent." Intracranial aneurysms are the result of congenital defects in the arterial walls, oftenest in the circle of Willis, septic or sterile emboli, arteriosclerosis or a combination of congenital defects and arteriosclerosis.[4] Subarachnoid hemorrhage from a brain tumor or from a sclerotic artery occurs infrequently, and the subarachnoid bleeding which sometimes occurs in blood dyscrasias, Hodgkin's disease, acute hemorrhagic encephalitis and acute glomerulonephritis is usually not great in amount.

Hemorrhage into the subarachnoid space may occur at any age, but it is commonest in the third, fourth, fifth and sixth decades of life. There is no significant sex difference. According to Martland,[5] 2 per cent of sudden deaths from natural causes are the result of spontaneous subarachnoid hemorrhage. Moritz and Zamcheck,[6] in a series of 1,000 cases of sudden and unexpected death in young soldiers, found that 6.9 per cent were due to hemorrhage from a ruptured intracranial aneurysm.

The index to definitive treatment is an accurate diagnosis both as to the location and as to the type of the pathological process. A roentgenogram of the skull may show a curvilinear streak, erosion of one side of the sella turcica, sharpening of one anterior clinoid process or shift of the pineal gland. The electroencephalogram may reveal focal abnormalities, and the visual fields may give some indication of the side of the lesion. Relief of headache by percutaneous occlusion of one carotid artery and not of the other is strongly suggestive of the side of the aneurysm.[7] However, none of these signs is sufficient to indicate the best method of treatment. With every patient under the age of 60 who has no specific contraindications, the percutaneous method of arteriography should be carried out early, usually between the seventh and the tenth day after the hemorrhage. Arteriography is also used in selected cases of

patients over the age of 60. If necessary, both carotid arteries and one vertebral artery are injected to outline the aneurysm, and hence to dictate the best method of therapy. In fact, it is best to do bilateral carotid arteriograms to demonstrate the anomalies in distribution of the collateral circulation and to reveal multiple aneurysms, which are present in 10 per cent of the cases. The Matas test, compression of the carotid artery for 10 minutes and tests for sensitivity to iodopyracet (diodrast®) must be performed before the arteriographic study is done. Local and thiopental (pentothal®) sodium anesthesia is used unless there is a contraindication. Under thiopental anesthesia the patient is relaxed and hence is less likely to have more hemorrhage. He does not move when the iodopyracet is injected; so the roentgenograms are better. Thorotrast® (colloidal thorium dioxide) is used only when sensitivity to iodopyracet or severe arteriosclerosis exists. When thorotrast® is injected, the open method of arteriography is used.

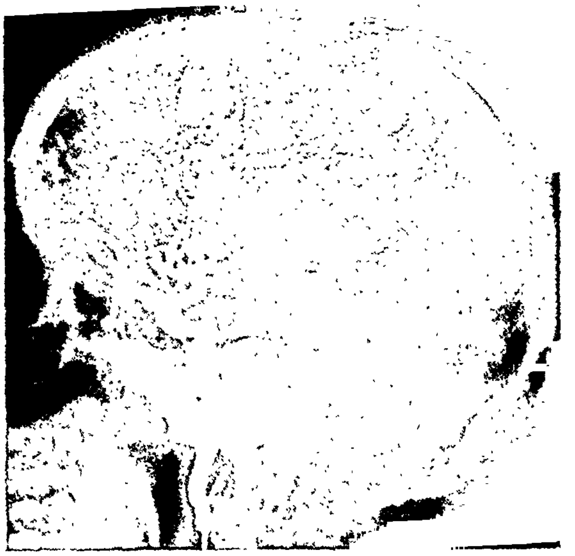

Fig. 1.—Lateral arteriogram showing arteriovenous aneurysm of the right frontal lobe. Arterial supply was from the anterior cerebral artery.

Surgical therapy consists in the direct intracranial approach to the aneurysm or in reduction of pressure and pulsation within the aneurysm by ligation of the arteries in the neck which supply the blood to the aneurysm. In order that the arteries in the neck may be safely ligated, there must be a sufficient amount of collateral circulation. An effort is made to determine this by carotid occlusion for 30 minutes. The vertebral artery cannot be satisfactorily compressed without exposing the artery, but in every case ligation is performed with local anesthesia. The patient is constantly questioned regarding symptoms; and strength, sensation and reflexes are checked at five minute intervals for the first half-hour and at 30 minute intervals thereafter for the first 24 hours.

Procedures in intracranial surgical therapy are removal of the aneurysm, trapping the aneurysm by applying clips to the artery on either side or by applying clips to the internal carotid artery in the neck and intracranially, clipping the neck of the sac, packing muscle around the outside of the wall of the aneurysm, opening the aneurysm and packing the cavity with muscle, and strategic clipping in some cases of arteriovenous aneurysm.

Every case is judged on its own merits. A direct intracranial attack on the aneurysm is the method of choice if the arteriogram demonstrates an aneurysm with a neck around which a clip may be applied, an aneurysm which can be removed or trapped by applying clips on either side or one which can be opened and the cavity filled with muscle. Packing muscle around the outside of the aneurysm to produce reinforcement of its wall apparently has some merit, at least in the cases reported, but the principles on which such treatment is based are not so good as they are in the other methods. With arteriovenous aneurysms complete removal is the method of choice, but when the aneurysm is in a vital area strategic clipping of contributing arteries or ligation in the neck is the method of choice. A large aneurysm at the junction of the anterior and middle cerebral arteries, or of the middle cerebral artery very close to its origin, is best treated by ligation in the neck. One anterior cerebral artery at or beyond the anterior communicating artery can be ligated safely in most instances. Hence, an aneurysm of the anterior cerebral artery beyond the anterior communicating artery can be removed or clipped and left in place.

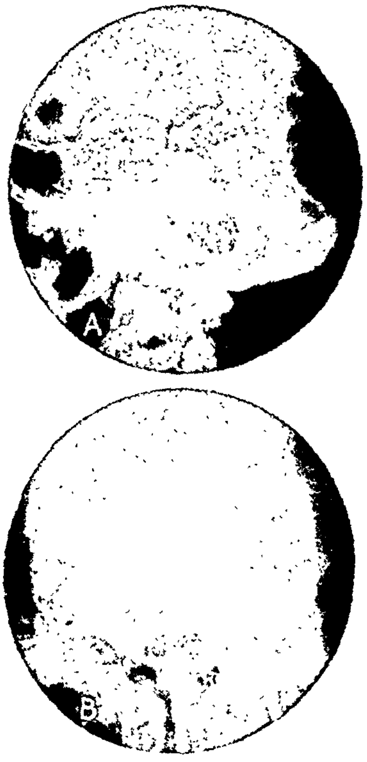

Fig. 2.—Anteroposterior and lateral arteriograms showing arteriovenous aneurysm in the right cerebellar region. Arterial supply was from the right anterior inferior cerebellar artery, pontile arteries and posterior inferior cerebellar arteries.

It is important to emphasize that in order to approach an aneurysm intracranially there must be facilities for an arterial transfusion, by means of which blood can be replaced as rapidly as it is lost, and a double suction apparatus to remove the blood quickly should the aneurysm rupture during its exposure, so that the bleeding point can be visualized and treated.

As many know, I am compiling an aneurysm registry, and neurosurgeons all over the United States and Canada are contributing their cases, in an attempt to establish basic indications for the various methods of therapy. The illustrative cases presented in table 1 are all of patients treated at the Neurological Institute of New York.

The mortality rate for conservatively treated patients is high. It was 48 per cent in 752 conservatively treated patients, which comprises the previously reported cases of spontaneous subarachnoid hemorrhage [8] and the present cases but excludes the series in which purely autopsy material was used (table 2).

Actually, the mortality rate would be even higher were the patients followed long enough. In 1893 Gowers [9] said:

> If the diagnosis of an intracranial aneurysm is certain, the prognosis is extremely grave. The probability that death will result is very great, and the duration of life most uncertain, since it is impossible to say how near or how distant may be the fatal rupture.

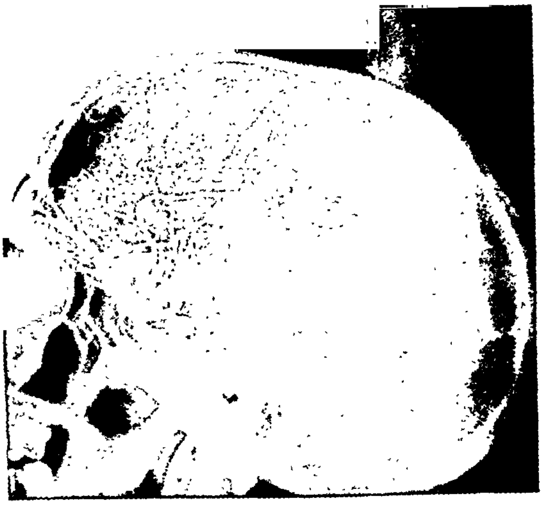

Fig. 3.—A lateral arteriogram showing a saccula aneurysm of the right posterior communicating artery.

Rosen and Kaufmann [10] reported a recurrent hemorrhage after 27 years, and Strully, in a personal communication, reported one after 25 years. There is, then, a constant danger of further hemorrhage and death in any patient who has had one hemorrhage.

The mortality rate for the 469 operatively treated patients was 14 per cent. This is the average of the reported cases,[11] including our own (table 3).

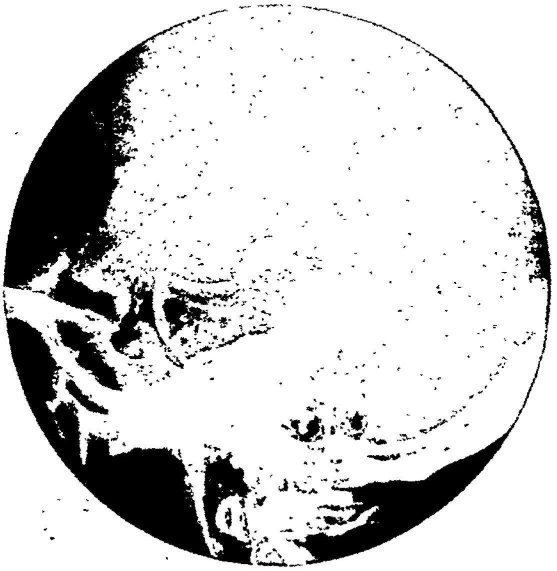

Fig. 4.—A lateral arteriogram showing a saccular aneurysm of the left posterior cerebral artery.

The mortality rate was 11 per cent for 77 consecutive patients with intracranial aneurysms treated by operation at the Neurological Institute. Further analysis revealed that the condition of 71 per cent (55 patients) was improved; that of 14 per cent (10 patients) was unimproved, and that of 4 per cent (3 patients) was worse. Twenty-one patients had an intracranial operation. Of

TABLE 1.—*Cases Illustrative of Spontaneous Subarachnoid Hemorrhage Due to Intracranial Aneurysms*

Case No.	Patient Age, Yr.	Symptoms	No. of Hemorrhages	Length of History	Signs	Arteriogram	Treatment	Results	Length of Follow-Up Observation
					Arteriovenous Aneurysms				
1 (fig. 1)	V. W. 19	Frontal headaches; vomiting; convulsions; coma	1	3 mo.	Weakness of left extremities; papilledema with hemorrhages	Right frontal arteriovenous aneurysm; arterial supply chiefly from anterior cerebral artery	Block incision	Condition improved; one convulsion when anticonvulsant medication was decreased, but none since	1 yr.
2 (fig. 2)	R. B. 28	Awkwardness of right extremities; diplopia; vomiting; occipital headaches	2	3 yr.	Right cerebellar; no papilledema	Arteriovenous aneurysm; arterial supply from right anterior inferior cerebellar artery, pontile arteries and posterior inferior cerebellar artery	Strategic clipping of contributing branches and ligation of right vertebral artery	Improvement	2½ yr.
					Aneurysms of Internal Carotid Artery				
3	A. C. 55	Sudden onset of lacrimation of left eye, severe throbbing pain above left eye and in left temporal region, drooping of left eyelid, inability to move left eye, nausea and vomiting	0	1 wk.	Blood pressure 170/94; cataract in left eye; complete ophthalmoplegia on left; ptosis on left	Saccular aneurysm of cavernous portion of left internal carotid artery, partly thrombosed	Multiple ligation in three stages: (1) left common carotid artery, (2) left internal carotid artery in neck, (3) left internal carotid artery intracranially	Improvement	6 mo.
4	F. M. 50	Sudden onset of pain in and around right eye, spreading to top and back of head, back and down back of legs; drooping of right upper eyelid; blurring of vision; drowsiness	1	2 days	Blood pressure 180/90; ptosis right; dilatation of right pupil; absence of pupillary reaction to light on right; paralysis of all extraocular muscles; decreased corneal reflex bilaterally; slight weakness of left grip; equivocal Babinski and Chadock signs on left; mild nuchal rigidity; positive Kernig sign	Saccular aneurysm of right internal carotid artery	Right common artery ligated while aneurysm still bleeding; 1 wk. later external carotid artery ligated; ligation of internal carotid artery planned, but vessel partly thrombosed	Improvement	2 yr.
					Aneurysms of Posterior Communicating Artery				
5 (fig. 3)	G. B. 34	Sudden onset of headache, pain in right frontal and temporal regions, ptosis of right eye, diplopia	0	3 mo.	Nasal hemianopsia in right eye; complete paralysis of muscles supplied by right third and fourth nerves; primary optic atrophy, right	Saccular aneurysm of right posterior communicating artery	Clipping of neck of aneurysm	Condition improved	2 yr.
					Aneurysm of Posterior Cerebral Artery				
6 (fig. 4)	E. S. 24	Recurring frontal headaches all of life; sudden onset of dizziness and fulness in head; a few hours later sudden loss of consciousness, tonic seizure; stiffness of neck, severe occipital headache, nausea and vomiting on regaining consciousness; three similar episodes within next four weeks	4	4 wk.	Pregnancy of 7 mo.; apathy; fulness of veins of retina; bilateral paresis of external rectus muscles; decreased reflexes, with left greater than right; positive Babinski sign on left; left central facial paresis; mild nuchal rigidity	Saccular aneurysm of left posterior cerebral artery	During 5th hemorrhage, with patient in opisthotonos, clip placed on posterior cerebral artery at site of origin of aneurysm; bleeding stopped; large clot evacuated from temporal lobe	Patient died 10 days postoperatively *	....
					Aneurysm of Anterior Cerebral Artery				
7	A. S. 55	Sudden onset of suboccipital and bitemporal hearache with transient inability to see; unsteadiness in walking; confusion	1	4 days	Fine tremor of hands; papilledema; right central facial paresis; stiffness of neck	Saccular aneurysm of left anterior cerebral artery	Ligation of left internal carotid artery; anterior cerebral artery clipped on either side of aneurysm	Condition improved	1 yr.
					Aneurysm of Anterior Communicating Artery				
8 (fig. 5)	J. S. 32	Sudden onset of severe headache, nausea and vomiting, followed by unconsciousness of 12 days' duration; daily morning headaches since then	1	2 mo.	Slight weakness of left upper extremity; slight dysmetria on left; slight hyperreflexia of right lower extremity; blurring of nasal margin of optic disks; right central facial paresis; positive Matas reaction bilaterally	Saccular aneurysm of anterior communicating artery	Incision into aneurysm and cavity packed full of muscle; cauterization of muscle to wall of aneurysm to hold it in place	Condition improved and patient asymptomatic	1 yr.

* Autopsy revealed compression of left hippocampal gyrus and tectum and tegmentum of midbrain; rupture of aneurysm into left temporal lobe and subarachnoid space; encephalomalacia, recent, of right and left fusiform and lingual gyri and pons; hemorrhagic pulmonary edema, bilateral; no hemorrhage from aneurysm after operation.

these, 86 per cent (17 patients) showed improvement, and 14 per cent (4 patients) died. Of the four who died, three were operated on when comatose and actively bleeding, in a desperate last resort to save the patient's life.

It is clear that the mortality rate of 14 per cent for the surgically treated patients is substantially better than the mortality rate of 48 per cent for the conservatively treated ones. It is therefore advisable to outline clearly the pathological process by arteriography and to perform the surgical treatment indicated.

Mortality rate 14%

SUMMARY

1. Spontaneous subarachnoid hemorrhage accounts for death in 2 per cent of the patients who die suddenly of natural causes.

2. It is caused by the rupture of an intracranial aneurysm in the great majority of patients.

3. It may occur at any age, but it is commonest in the third, fourth, fifth and sixth decades of life.

4. It is characterized by the sudden onset of severe headache, stiffness of the neck, vomiting, collapse and, in many instances, coma.

5. *Arteriography* is essential to establish the diagnosis, both as to the location and as to the exact type of pathological process. Only then can definitive treatment be undertaken.

6. The mortality rate was 48 per cent for the medically treated patients. This represents the average mortality rate for 752 cases, including several large series previously reported and the present series.

7. The mortality rate was 14 per cent for the surgically treated patients. This represents the average mortality rate for 469 cases, including the reported cases and our own.

8. When it is possible, direct intracranial surgical treatment is the best method of therapy.

ABSTRACT OF DISCUSSION

Dr. Bernard J. Alpers, Philadelphia: Dr. Mount has demonstrated clearly what has now become quite evident, that cerebral aneurysms are amenable to operation and that operation effectively reduces the mortality by the prevention of rupture of the aneurysm. The statistical figures favor strongly the surgical treatment of the disorder, whether it be by extracranial or by intracranial approach or by a combination of the two. It is important to recognize, however, that, while operation may prevent rupture of the aneurysm, it does not necessarily result in recession of the symptoms. The headache is usually corrected, but the ocular palsies, visual disturbances, hemipareses and other symptoms may persist despite operation. There are relatively few patients, however, who would not put up with a persistent unilateral ophthalmoplegia in exchange for absence of headache and the threat of rupture of the aneurysm. It would be valuable to know whether Dr. Mount has any statistics concerning the frequency of disappearance of symptoms after operation. Despite an increasing recognition of the aneurysm syndrome, the unfortunate position of diagnosing the aneurysm after rupture is too frequent. Once rupture with subarachnoid bleeding occurs, the problem becomes an emergency. It is desirable, therefore, to make the diagnosis before subarachnoid hemorrhage develops. The diagnosis should be considered in cases with recurrent unilateral headache associated with or followed by cranial nerve paralyses of one type or another. Most frequently the optic and ocular nerves are involved because of the greater concentration in the anterior part of the circle of Willis, but it must not be forgotten that any of the cranial nerves may be affected and that hemiplegias may develop with aneurysms of the middle cerebral artery. Once the diagnosis is suspected, it may be made readily by arteriogram, though I have not regarded arteriography as a necessary routine procedure. As Dandy pointed out, the diagnosis may be established without arteriographic studies. While the arteriogram will disclose the larger aneurysms and vascular anomolies, it fails to reveal the miliary aneurysms associated with spontaneous subarachnoid hemorrhage. Unfortunately, these aneurysms, unlike the larger variety, fail to give warning of their presence until they rupture, and, while some patients die in their first attack, many patients survive and live in fear of recurrent rupture. Possibly the arteriogram may offer some means of detecting them, but visualization of all the main branches of the cerebral circulation bilaterally is essential. It is a goal worth seeking, and it seems to be one of the most important of the unsolved problems of aneurysm.

Dr. Tracy J. Putnam, Beverly Hills, Calif.: No doubt this condition is less benign than was formerly taught. It is important to make a definite diagnosis as promptly as possible and initiate appropriate treatment. However, several important questions remain unanswered by the statistical studies as yet published. First, how far is it wise to push the surgical attack? Actual ligation and excision of an aneurysm should produce a permanent cure, but it is an operation necessarily attended with considerable risk. In some cases, long-continued relief follows ligation of the internal carotid artery, a procedure which should entail a negligible mortality rate. What proportion of patients are subject to relapse after a carotid ligation? Do we know what procedure offers the best compromise between the two extremes? I have adopted the policy of routine carotid ligation as an immediate step, followed by further intracranial procedures only as indicated. Of two minor technical points which I have found useful, one is to practice repeated drainage of spinal fluid, once the carotid ligation has been performed. This shortens convalescence and perhaps minimizes cortical damage. The second is to use a strip of polyethylene film to ligate the common carotid artery and a strip of cellophane to narrow the lumen of the internal carotid artery, at the time of the arteriographic study or subsequent surgical procedure. This polyethylene film may be removed quickly if hemiparesis develops, while the presence of the band of cellophane gradually chokes off the circulation in the internal carotid artery.

Dr. Harold C. Voris, Chicago: Dr. Mount has clearly shown the advantage of surgical treatment in these cases. The statistical difference in favor of surgical treatment is even more striking when one considers that the data in a large number of the cases that he has analyzed were presented him by neurosurgeons who at the time the treatment was carried out had relatively little operative experience with these lesions. The increasing use of angiography now provides a means, not only of localizing the aneurysm accurately, but of determining the adequacy of the circle of Willis, that is, the adequacy of the collateral circulation. The establishment of those two points is essential before any planned attack on an aneurysm is carried out. I believe that in the next few years it will be possible for many neurosurgeons, with the aid of angiography and with the newer methods of preventing the complication of thrombosis after ligation of the carotid artery to improve greatly the statistics reported to date. As Dr. Mount points out, mortality of 11 per cent in the series of cases from his institution is considerably less than that for the group as a whole. James Poppen reported recently a series of 143 cases, with a mortality rate of only 7 per cent. Even those figures, I think, will eventually be improved on.

Dr. Walter F. Schaller, San Francisco: The nonoperative mortality as given by the author is much higher than that in my own experience, which is admittedly slight, as compared with the total number of reported cases. I observed a young man in a country town, undoubtedly suffering from a subarachnoid hemorrhage, whose condition was so serious as to court danger either on his removal to a city hospital or on his undergoing angiographic study. He is now greatly improved. Of course, it is known there is danger of a subsequent fatal attack—had this man been operated on and survived, he might still be in the eventual mortality group, as correlated with the long statistical period covered by the nonsurgical cases. I should like to ask Dr. Mount, therefore, to elaborate on his statistical data, particularly as to the time elapsed since operation, and to state whether the nonoperative group includes patients not referred to the surgical clinic, including those with less severe conditions, often first mistakenly diagnosed as apoplexy.

Dr. Lester A. Mount, New York: Regarding the frequency of the disappearance of symptoms after operation, I cannot quote the exact statistics. Most of the patients did have some residuals secondary to the hemorrhage. In answer to Dr. Putnam's question, "How wise do you feel it is to pursue the surgical attack?" Every case must be judged on its own merits. I believe some form of surgical attack is feasible in the great percentage of cases, either the direct intracranial approach to the aneurysm or ligation in the neck. If nothing is done, most of the patients will have another hemorrhage. As mentioned in the paper, a second, fatal hemorrhage has been reported as long as 27 years after the first hemorrhage had occurred. In answer to Dr. Schaller's question, the mortality rate was 48 per cent for over 700 patients without any operative therapy. Of the surgically treated patients, three of those attacked intracranially were actively bleeding and would obviously die unless something was done for them. These three did die. Of course, had we refused to operate on those patients, our mortality rate would have been even lower. We are operating on patients early, while they are actively bleeding, either by ligation in the neck or by an intracranial approach, depending on the results of the arteriography. I am interested in what will happen to those patients who have had a subarachnoid hemorrhage and in whom complete arteriographic studies of both carotid arteries and of the vertebral artery have shown no aneurysm. Do these patients have a better prognosis? That is something we can answer only with the passage of time. It is recommended that the intracranial approach be used whenever possible. Of our patients who had ligation in the neck alone, two have subsequently hemorrhaged and died. I find that many other neurosurgeons have had a similar experience. I therefore recommend that the intracranial approach be used whenever feasible.

Knowledge.—The best part of our knowledge is that which teaches us where knowledge leaves off and ignorance begins. Nothing more clearly separates a vulgar from a superior mind, than the confusion in the first between the little that it truly knows, on the one hand, and what it half knows and what it thinks it knows on the other.—Oliver Wendell Holmes, Medical Essays, Boston, Houghton, Mifflin and Company, 1883.

FRACTURES OF THE ELBOW IN CHILDREN

Walter P. Blount, M.D., Irwin Schulz, M.D.
and
Robert H. Cassidy, M.D., Milwaukee

Fractures about the elbow in children are different from those in adults. Bone growth after the fracture is responsible for the difference. Continued growth is important for several reasons: A fracture increases the blood supply to the bone, which accelerates the rate of growth; this tends to equalize shortness from overriding. Growth will correct some angular deformities near the ends of long bones. However, a fracture involving an epiphyseal cartilage may retard growth so as to cause shortening or angular deformity.

Fractures at the elbow joint are very common in children. They follow patterns so remarkably constant that they may be discussed in groups. While each fracture must be evaluated and treated individually, certain general rules may be established.

In children, fractures may be well treated by simple conservative means more frequently than in adults. The exceptions to this are almost all fractures at the elbow joint. Fractures of the lateral condyle, the medial epicondyle, and the neck of the radius are usually best treated by open reduction. All other fractures about the elbow can be treated satisfactorily by traction or closed reduction.

FRACTURES THAT CAN BE TREATED WITHOUT OPERATION

Supracondylar (transcondylar) fractures, which comprised 268, or 60%, of 453 consecutive elbow fractures, can be treated without operation. A transverse fracture line through the olecranon fossa is produced by hyperextension of the elbow, usually from a fall on the outstretched hand. The fracture is either incomplete and with anterior angulation or complete with posterior displacement of the distal fragment and overriding. If the fracture is seen promptly, an excellent result will usually be obtained by closed reduction and immobilization in flexion (fig. 1). If reduction is delayed and swelling has appeared, it is often better to apply traction (fig. 2).

Less than 1% of supracondylar fractures are of the reversed or flexion type. These are produced by a fall on the flexed elbow, with resultant anterior displacement of the distal fragment. This flexion fracture should be reduced and immobilized in sufficient extension to prevent the recurrence of the angular deformity. It is a mistake to confuse the treatment of this fracture with that of the commoner extension type.

The risk of complication is great in all complete supracondylar fractures. Impairment of circulation and nerve injury depend on the initial trauma and the subsequent handling. The greatest danger is Volkmann's ischemia. Prompt, gentle reduction and immobilization without constriction offer the best defense. Supracondylar fractures are treated as emergencies.[1]

Many arguments are offered for the open reduction of supracondylar fractures. If there is ever a real indication in the absence of compounding, it is extremely rare. With gentleness and patience, a good result may be obtained without operation. The use of internal fixation for the supracondylar fracture that slips off after closed reduction is a sign of impatience on the part of the surgeon. Suspension of the forearm with suitable traction for a week or 10 days will allow the swelling to subside.[2] Manipulation under anesthesia and fixation in flexion will then be successful.

Comminuted supracondylar fractures and "T" fractures occur rarely in children. If seen promptly, they can be treated most satisfactorily by manipulation under anesthesia and the application of a hanging cast (fig. 8). It is amazing to see a confused jumble of fragments fall into position when traction is combined with gentle molding. A critical analysis of the end results argues for the closed methods; there is too often permanent limitation of motion after operation.

Before reduction of any elbow fracture, careful examination should establish the normal function of the motor nerves controlling the hand and the condition of the radial pulse. If the pulse is present, it should not be obliterated by the manipulative reduction. If absent before manipulation, it may be disregarded if the capillary circulation remains good. An absent radial pulse per se is not an indication for open reduction.

The mechanics of closed reduction are simple (fig. 1). While countertraction is made in the axilla, straight traction is made on the supinated wrist with one of the operator's hands. The other hand grips the arm just above the elbow with the fingers over the biceps. The thumb lies against the distal end of the proximal fragment while hyperextension is made to disengage the fragments. Malrotation of the fragment is corrected by varying the degree of supination. Lateral displacement is corrected by molding the fragments before correcting the posterior displacement. Then the thumb slips down over the tip of the olecranon, forcing the distal fragment forward into position. Counterpressure is supplied by the fingers. The elbow is flexed only after complete reduction of the fracture. The position is checked at once by roentgenograms. If it is not satisfactory, a second reduction may be tried. Traction in bed is preferable to the insult of many manipulations.

Fixation in flexion may be variously achieved. The simplest and surest method is to join a collar and cuff by an inelastic bandage (fig. 1 *D*). A light compression dressing about the elbow retards swelling and increases the child's comfort. The addition of a plaster splint to hold the forearm in supination is advocated by some.

Read before the Section on Orthopedic Surgery at the Ninety-Ninth Annual Session of the American Medical Association, San Francisco, June 28, 1950.

[1] Schulz, I.: Fractures of the Elbow in Children, Wisconsin M. J. 36:913, 1937.

[2] Dunlop, J.: Transcondylar Fractures of the Humerus in Childhood, J. Bone & Joint Surg. 21:59, 1939. Allen, P. D., and Gramse, A. E.: Transcondylar Fractures of the Humerus Treated by Dunlop Traction, Am. J. Surg. 67:217, 1945.

The rotation of the forearm is unimportant once reduction has been obtained. Adhesive plaster dressings are secure—too secure. Unless applied with extreme care, they are a threat to circulation. Some of the worst cases of Volkmann's ischemia have occurred with the use of adhesive plaster dressings.

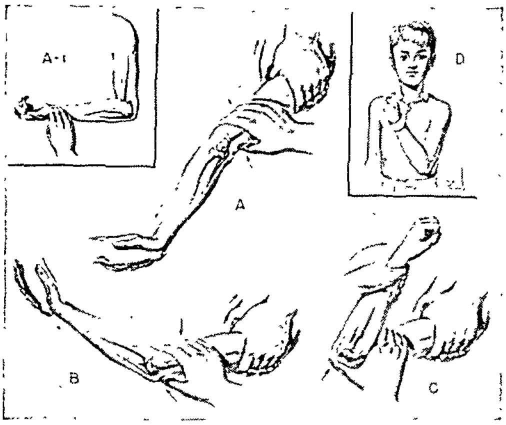

Fig. 1.—Reduction of a supracondylar fracture. *A*-1, determine the presence or absence of the radial pulse; examine for motor paralysis. *A*, reduction under general anesthesia. Traction is applied and the elbow hyperextended. *B*, the surgeon's thumb forces the distal fragment into position. Accurate reduction is obtained by rotation of the forearm and molding at the site of the fracture. *C*, only after the fracture is completely reduced is the elbow flexed acutely (not forcibly). *D*, reduction is maintained by the flexed position that is assured by an efficient collar and cuff.

After reduction of the supracondylar fracture, the child should be hospitalized for 24 hours to insure frequent observation of the circulation of the hand by a competent nurse or house officer. If this is not possible, the parents must understand the danger signals. Most significant as warnings of early ischemia are pain, swelling, coldness, cyanosis or pallor, and paralysis of the hand. The most important and constant of these signs is pain. A child with a well-reduced fracture should not require sedatives other than acetylsalicylic acid (aspirin). Pain severe enough to require use of opiates should be a warning that there is disturbed circulation.

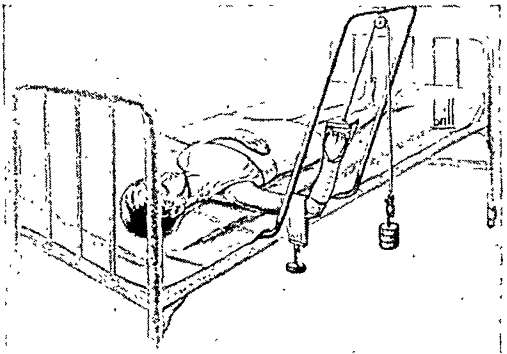

Fig. 2.—Dunlop's traction as modified by Allen and Gramse[2] is used temporarily if there is excessive swelling or threatened vascular embarrassment. It may be continued until healing is complete.

Complications.—If there is evidence of circulatory embarrassment and threatened ischemia, all bandages are removed from the elbow and forearm, angulation is reduced to about 120 degrees, and ice bags are applied. Satisfactory position of the fragments and elevation of the forearm are maintained by traction. Usually this may be applied to the skin of the forearm without constriction (fig. 2), but traction by means of a Kirschner wire through the olecranon[3] or even the base of the thumb may be preferable. Loss of position of fragments is insignificant compared to the permanent disability following unrelieved ischemia.[4] Prompt blocking of the appropriate sympathetic ganglions is frequently effective. If the symptoms are well advanced or do not subside with conservative measures, no time should be lost before exploring the cubital fossa and volar aspect of the forearm. The tough fascia enclosing the flexor muscles of the forearm is slit, permitting the explosive extrusion of edematous muscles and hematoma. An injured or markedly constricted brachial artery should be resected. This relieves vasospasm and the reflex involvement of the intimate vasculature of the muscles.[5] Delay is disastrous. Within three or four hours irreversible changes have taken place. The all-too-frequent claw hand usually means inadequate or delayed therapy.

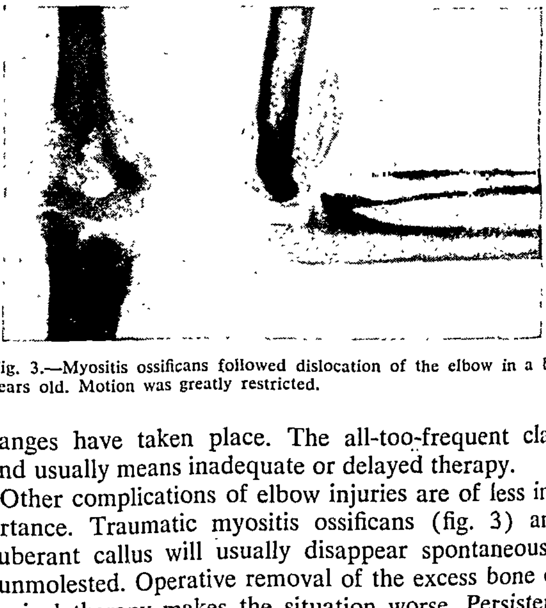

Fig. 3.—Myositis ossificans followed dislocation of the elbow in a boy 6 years old. Motion was greatly restricted.

Other complications of elbow injuries are of less importance. Traumatic myositis ossificans (fig. 3) and exuberant callus will usually disappear spontaneously if unmolested. Operative removal of the excess bone or physical therapy makes the situation worse. Persistent capsular contracture may require excision of the anterior capsule.[6] Reversal of the carrying angle (gun stock deformity) may be due to uncorrected medial displacement of the distal fragment, usually because of rotation. It may follow a perfect reduction because of accelerated growth of the lateral condyle, but rarely results from retarded growth of the medial condyle. Paralysis from nerve injury is usually only temporary.

Aftercare.—In the average case the elbow should be immobilized in flexion for about three weeks. At the end of that time the callus is hard enough to allow the elbow to be lowered to a right angle in a sling. In another week or two, all fixation may be discontinued and the child allowed to use the hand at his own discretion. It has been adequately proved that more rapid return of normal function will occur if the child is unmolested. Carrying pails of sand does more harm than good. There should be no manipulation to increase motion either with or without anesthesia. Repeated stretching of contractures not only distresses the child but perpetuates the spasm and delays the return of normal function.

Occasionally there is an indication to continue traction until callus is solid. When angular deformity persists at the end of three or four weeks, the fracture may be manipulated under anesthesia and satisfactory position obtained. Bayonet apposition with normal alignment is satisfactory and is not an indication for manipulation at this stage. As in fractures of other long bones, sharp edges round off as growth continues.

FRACTURES THAT REQUIRE OPEN REDUCTION

Fractures of the lateral condyle (84, or 18.5%, of 453 consecutive elbow fractures) require open reduction. The fracture line extends from the lateral epicondyle obliquely downward and medially into the trochlea. The deformity is not great, and the injury is often dismissed as a sprain. The roentgenographic diagnosis is difficult in very young children because a large portion of the distal end of the humerus is still cartilaginous. The oval osseous center of the capitellum may be the only bone visualized in the condylar fragment, but usually a flake of metaphyseal bone is carried with it. The fragment is larger than appears in the roentgenograms. It is characteristically rotated laterally and downward by the pull of the extensor muscles and trapped in the joint, so that the articular cartilage of the capitellum comes to lie against the raw surface of the metaphysis (fig. 5*A*).

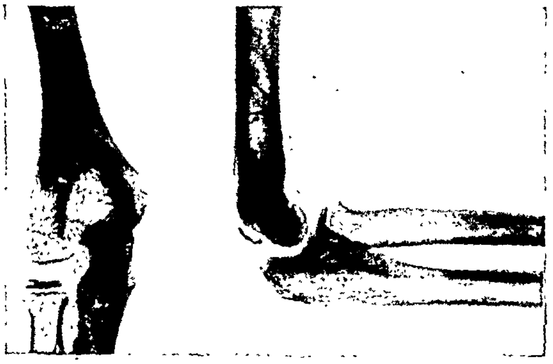

Fig. 4.—Roentgenogram taken three years later of the elbow shown in fig. 3. The excess bone has almost disappeared Elbow motion is normal. No treatment was given. Operation is contraindicated in children.

If the fracture is untreated, nonunion almost always occurs (fig. 6). With growth, the carrying angle becomes exaggerated. The end result is a painful, weak, deformed elbow. The most significant disability is delayed ulnar nerve palsy, which comes on about 20 years after the injury (fig. 7). When the displacement is marked, attempts at closed reduction are futile. Rarely, the fragment may be jockeyed into normal position, but it will not stay there without internal fixation. It is much better to do an immediate (within five days) open reduction with pin fixation than to operate two weeks later because the fracture has slipped. When the operation is delayed, it is more difficult and may cause overgrowth. Retardation of growth has not been encountered.

In the case with only slight initial displacement, there may be sufficient continuity of the soft parts to keep the fragment in position. Closed reduction may improve the position, and open operation may be unnecessary. Check-up roentgenograms should be obtained at two and five days. The fragments frequently slip soon after reduction.

The Operation.—The open reduction of a lateral condylar fracture is best accomplished through a Kocher incision (fig. 5*A*-1). A tourniquet is not necessary. After the clotted blood has been removed from the raw surfaces with a curet, the mobile fragment may be pulled into position with sharp hooks. An accurate fit should be obtained. Two obliquely placed short pins are efficient in holding the fragment. The periosteum is sutured, but

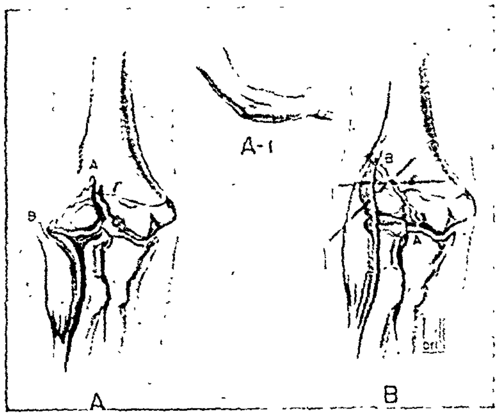

Fig. 5.—*A*, fracture of the lateral condyle. The extensor muscles of the forearm frequently rotate the fractured surface *AB* laterally and downward through an arc of 90 degrees or more. The osseous centers of the capitellum and the medial epicondyle are indicated in white. *A*-1, open reduction is performed through a part or all of the Kocher lateral incision. *B*, the rotated condylar fragment has been pulled back into position with small bone hooks. The fractured surface *AB* has its normal position. The fragment is fixed with two pins, which are allowed to protrude slightly under the skin. The aponeurosis of the extensor muscles is sutured.

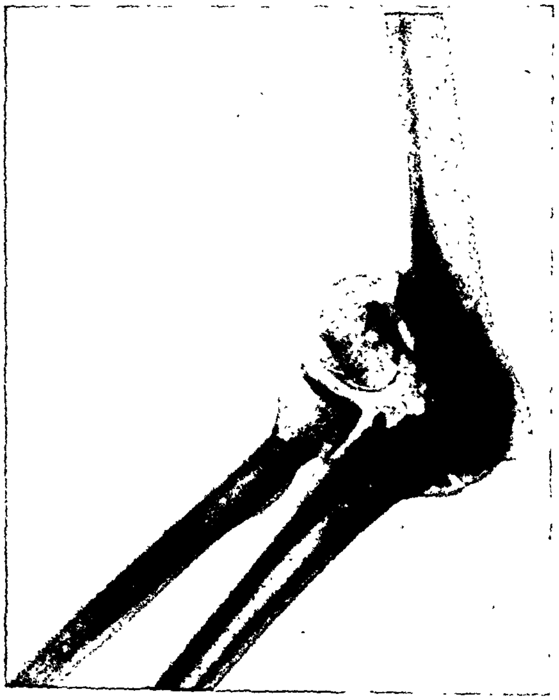

Fig. 6.—Anteroposterior roentgenogram of the elbow of a 21 year old man who had an untreated lateral condylar fracture at 2 years of age. There were weakness and pain from the nonunion of the condyle; early symptoms of ulnar nerve trauma resulted from the increased carrying angle.

this alone is not enough fixation. The pins may be left slightly long so that they protrude under the skin (fig. 5 *B*). After closure of the wound, a cast is applied from the knuckles to the axilla with the elbow in flexion of 90 degrees (fig. 8) and the forearm in neutral rotation.

At the end of three weeks the stitches are removed through a window in the cast. If they have not already pushed through the skin, the pins are exposed with a pointed knife and pulled out. A week later the cast may be removed and replaced by a sling. Long term (10 to 15 years) follow-up of fractures treated by open reduction has shown the results to be uniformly satisfactory. Growth arrest or significant limitation of motion has not been observed.

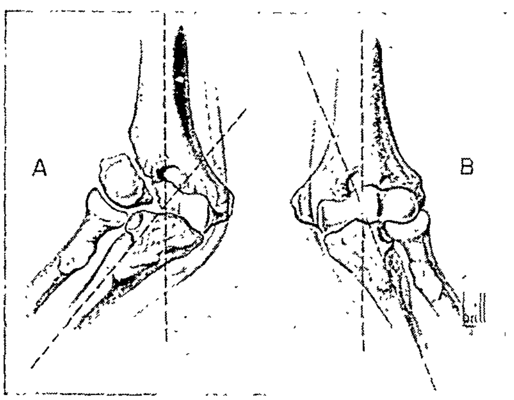

Fig. 7.—Nonunion usually occurs in untreated lateral condylar fractures in young children. With growth the carrying angle increases. Compare with the normal side *B*. Years of trauma to the ulnar nerve result in the characteristic picture of delayed ulnar nerve paralysis.

FRACTURES OF THE MEDIAL EPICONDYLE

Fractures of the medial epicondyle made up 8%, 38 cases, of the present series. Medial epicondylar avulsion is the result of sudden valgus strain of the elbow. It commonly occurs with dislocation of the elbow joint. If the apophysis is displaced only a few millimeters, the aponeurosis of the flexor muscles is probably not completely torn. Brief immobilization in flexion is all that is necessary. Bony healing will usually take place without deformity or disability. If the displacement is greater than 5 mm., one must decide between leaving the fragment displaced and opening the fracture and pinning the fragment in its normal position. Attempts at closed reduction are fruitless. If the displacement is allowed to persist, nonunion is the rule. Usually there is slight deformity but no disability. In girls this may be more desirable than a scar. Occasionally the displaced fragment is reunited to the metaphysis by a hornlike bony projection.

With marked displacement of the epicondyle there may be associated symptoms of ulnar nerve injury. The fragment of bone with the attached flexor muscles may be incarcerated in the elbow joint. There may be considerable rotation of the fragment distally and medially. Any of these findings is an indication for open reduction, without which there will be deformity, weakness, and limitation of extension.

In a fresh case the fragment should be pinned back in position. The ulnar nerve may be exposed during the operation, but it is rarely injured and may be left in its groove. If operation is not done until two weeks after the injury, it is better to excise the fragment and suture the aponeurosis of the muscle to the humeral condyle. Open reduction and internal fixation performed four weeks or more after the injury are usually followed by only a fair result and prompt operation by an excellent one. The elbow should be immobilized in right angle flexion for four weeks postoperatively as described for lateral condylar fractures (fig. 8).

FRACTURES OF THE RADIAL NECK

Twenty-one (4.5%) of the fractures in this series were of the radial neck. The force that produces a compression fracture of the radial head in an adult will fracture the radial neck in a child. Characteristically, the button-like osseous center with a thin flake of metaphysis is broken off transversely and pushed radially. If the displacement is only partial, so that there is some apposition and the angulation is 45 degrees or less, one may be able to manipulate the fragment so as to improve the position. Then the treatment should be conservative. A cast is applied with the elbow flexed to 90 degrees or more acutely. Whether the position is improved or not, with the 45 degrees of angulation the end result will be surprisingly good. After removal of the plaster, there will be a period of marked disability during which all motions are greatly restricted. Such disability may last for several months. The temptation is great to excise the radial head in order to increase the range of motion. While the immediate effect is favorable, the late results are tragic. In the cases that have been followed,[7] there has been gross deformity with radial deviation of the hand, shortening of the forearm, increase in the carrying angle, and weakness. Never excise the radial head in a growing child.

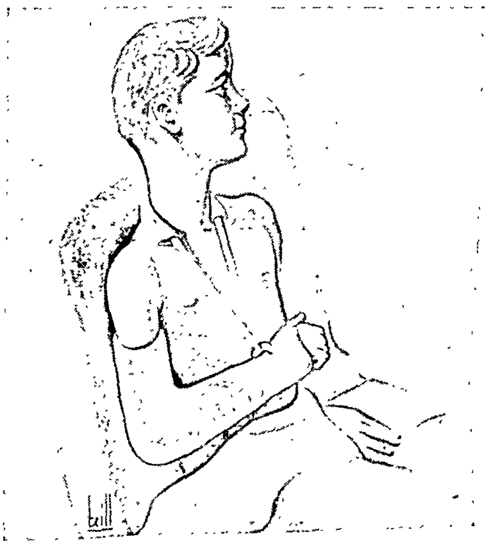

Fig. 8.—An arm cast with the elbow flexed is of great value in children's fractures. When it is used as a hanging cast to *maintain reduction* of a low humeral fracture, the elbow should be flexed more acutely than a right angle. For a few days the patient should sit almost upright with the elbow hanging free.

If the radial head is angulated 90 degrees and displaced off the shaft so that its fractured surface lies against the shaft, prompt open reduction is the treatment of choice. If the operation is performed in the first few days, the immediate and late results should be excellent. A bad prognosis [8] is not justified. Great care should be used in handling the epiphysis. It should be gently pulled into position with small hooks. When it is accurately replaced and the elbow flexed, rotation of the forearm will not displace the fragment. The flexed position should be maintained while the wound is closed and plaster applied. Internal fixation is undesirable and usually unnecessary.[9]

If the operative reduction is delayed or if the fracture is of the comminuted type, considerable new bone will be formed and motion will be restricted for some time. As in cases of traumatic myositis ossificans, the treatment should be conservative. Satisfactory motion will gradually return in most cases. Physical therapy is contraindicated. In the unusual case with pronounced restriction of radiohumeral motion, or in the very rare fracture of the head of the radius, operative resection of the head is indicated but should be postponed until the child is nearly full grown.

MISCELLANEOUS ELBOW INJURIES

Olecranon fractures (6%) may occur as isolated injuries in children. Fixation in extension is permissible. Not infrequently olecranon fractures are associated with dislocation of the radial head. If both are treated promptly, closed reduction is usually successful. Open reduction of a dislocated radial head may be necessary. Use the Boyd incision.[10] Fractures of the proximal third of the ulna associated with dislocation of the radial head (Monteggia) are rare in children (1.5%). They do not require internal fixation of the ulna as in adults.[11] When the radial head is reduced by manipulation or by open operation, the radius splints the ulna.

An old dislocation (three months) of the radial head in a child, either with or without associated fracture, should not be reduced by open operation. This dislocation causes no disability, although it may be unsightly. Delayed open reduction results in permanent limitation of motion. Excision of the radial head leads to the deformity and disability previously mentioned and is absolutely contraindicated. After the child is fully grown, the radial head may be excised.

Subluxation of the radial head in very young children is puzzling to the uninitiated. This common lesion is produced by a jerk on the upraised arm of a 2 to 4 year old child.[12] The subluxation is extremely painful. The child screams and resists all attempts at help. The roentgenograms show nothing abnormal. The diagnostic feature is limited supination. Forced supination produces an audible and palpable click associated with sharp pain. Motions then become normal, and the pain disappears. The elbow should be immobilized with a collar and cuff for a week to prevent recurrence of the subluxation.

SUMMARY

Elbow fractures in children are different from similar fractures in adults. With three exceptions, conservative treatment by manipulation or by traction is preferable to open operation.

In most fractures of the lateral condyle the treatment of choice is immediate open reduction and internal fixation.

Fractures of the medial epicondyle with marked displacement, with incarceration of the fragment in the elbow joint or with symptoms referable to the ulnar nerve, require prompt open reduction and internal fixation.

Fractures of the radial neck with minimal displacement should be treated conservatively; those with marked displacement should be reduced by prompt open operation without internal fixation.

Operation is contraindicated in children with dislocation of the radial head or fracture of the radial neck of longer than three months' duration and in children with myositis ossificans.

Complications are frequent in elbow fractures. The most serious complication is Volkmann's ischemia. When there is threatened circulatory embarrassment, the vascular problem becomes more important than the position of the fragments; prompt heroic measures are indicated.
